

Just Fast Keying ?

W. Aiello, S.M. Bellovin, M. Blaze, R. Canetti, J. Ionnidis, A.D Keromytis, and O. Reingold. Efficient, DoS Resistant, Secure Key Exchange for Internet Protocols. In *ACM Conference on Computer and Communications Security (CCS'02)*, November 2002.

Session establishment (again)

- Two parties want to open a secure session
 - Telnet (SSH)
 - Web connection (SSL, TLS)
 - IP tunnel (VPN)
 - Wireless network
- They need to
 - Generate a shared secret (the "session key")
 - Agree on many parameters
 - Verify each other's identity
- Attackers might eavesdrop, delete, and insert messages, may impersonate principals,... in order to
 - gain information
 - confuse or hinder the participants

Building blocks

- Shared-key encryption
- Cryptographic hash (HMAC)
- Tokens (or cookies)
- Diffie-Hellman computation
- Public-key signature

Two-round Diffie-Hellman

- Against active attackers,
first create a shared key, then authenticate

Complications

- Configuration
 - Different security needs according to the application
 - Many cryptographic algorithms to choose from
 - Many flavours of authentication (PKIs)
 - Different modes
- Concurrency
 - Parallel sessions
 - Various principals using several shared proxies
- Efficiency concerns
 - Round-trips are expensive
 - Cryptography can be expensive
- Session management
 - Key derivation
 - Rekeying
 - Dead peer detection

IKE and its successors

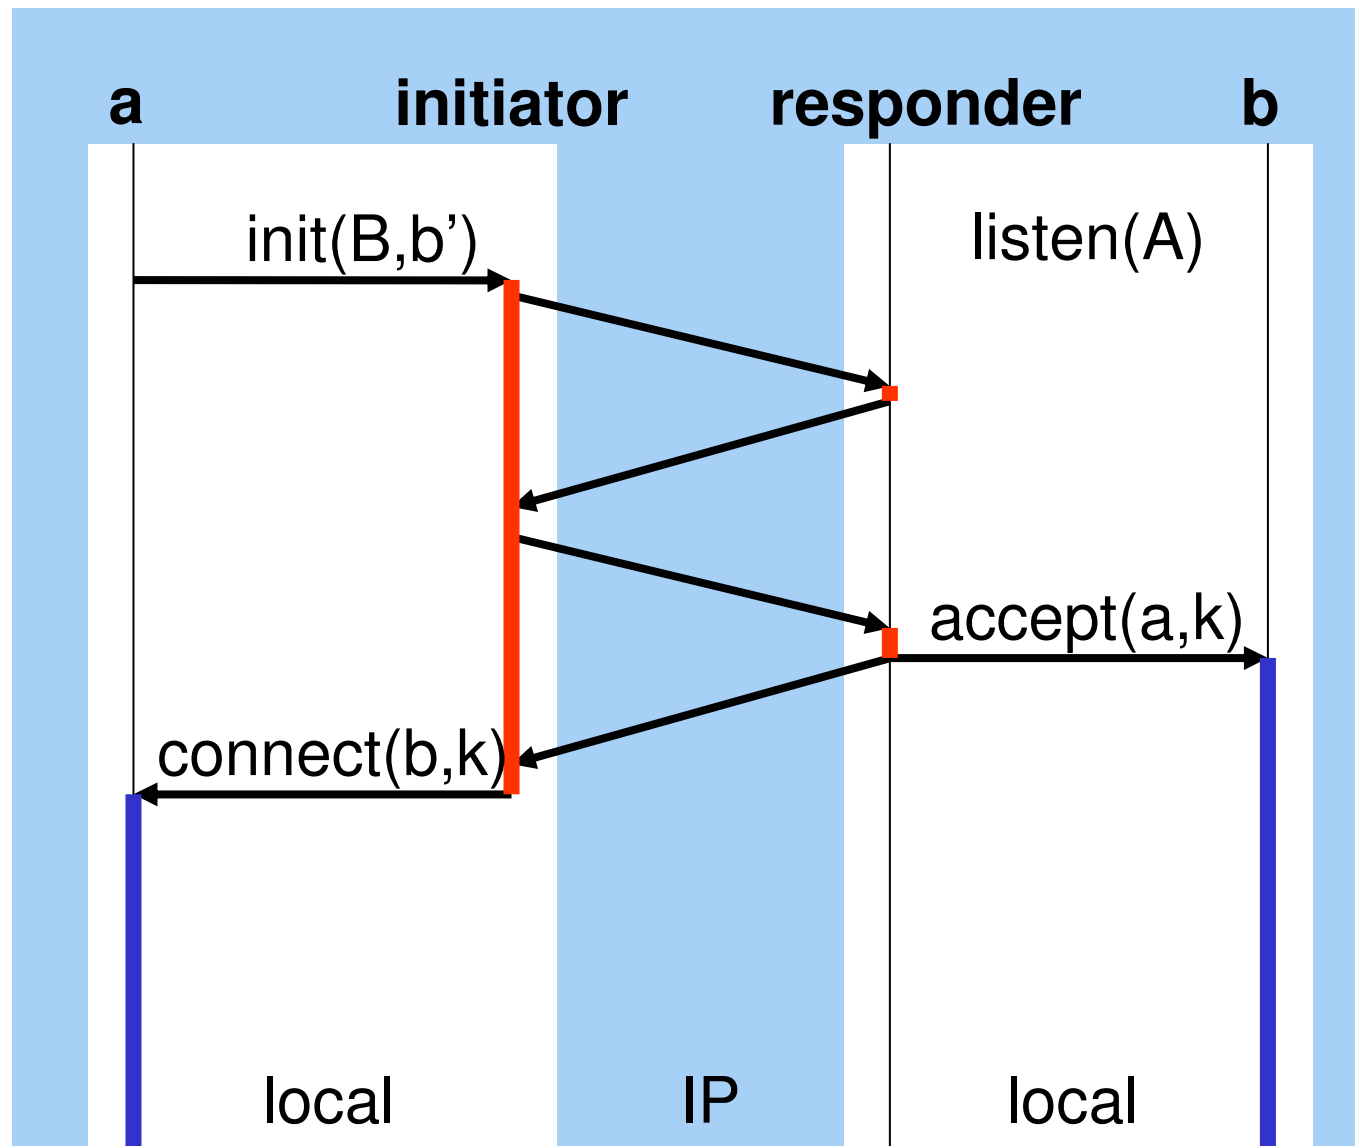

- IKE (Internet Key Exchange)
 - Session management for IPSEC
 - Quite secure
 - Some concerns
 - Too complicated
 - Inefficient (too many messages & expensive operations)
 - Poor resistance against denial of service
- The IETF is considering a successor for IKE, (now merging the different proposals into IKEv2)
- JFK (Just Fast Keying) is a simple proposal that incorporates several new mechanisms.
<http://www.ietf.org/internet-drafts/draft-ietf-ipsec-jfk-04.txt>

Design goals for JFK

- Security
 - “The key should be cryptographically secure, according to standard measures of cryptographic security for key exchange”
- Simplicity
- Resistance to Memory DoS
- Resistance to CPU DoS
- Privacy
 - Identity protection for some parties, against some classes of attacks
- Efficiency
- Non-negotiated
- “Flexible” perfect forward secrecy
 - With reuse of exponentials
- Plausible deniability

These goals are (sometimes) contradictory.

Using JFK

The JFKr protocol

- Msg 1 $i \rightarrow r : n_i, g^{d_i}$
- Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
- Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
- Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

- where $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, \text{IP}_i)$
- $e_i = \text{Encrypt}\{k_e\}(\text{id}_i, \text{id}'_r, \text{sa}_i, s_i)$
- $e_r = \text{Encrypt}\{k_e\}(\text{id}_r, \text{sa}'_i, s_r)$
- $s_i = \text{Sign}\{i\}(n_i, n_r, g^{d_i}, g^{d_r}, p_r)$
- $s_r = \text{Sign}\{r\}(g^{d_r}, n_r, g^{d_i}, n_i)$
- $k_u = \text{Hmac}\{g^{(d_i d_r)}\}(n_i, n_r, 'u')$ for $u = a, e, v$

The JFKr protocol: flexible PFS

- Msg 1 $i \rightarrow r : n_i, g^{d_i}$
- Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
- Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
- Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

where $IP_i = \text{Hmac}\{k_a\}(g^{d_r}, n_r, n_i, IP_i)$

The pair of nonces is unique to this session

$e_r = \text{Encrypt}\{k_e\}(id_r, s_r)$

$s_i = \text{Sign}\{i\}(n_i, n_r, g^{d_i}, IP_i)$

$s_r = \text{Sign}\{r\}(g^{d_r}, n_r, g^{d_i}, IP_i)$

$k_u = \text{Hmac}\{g^{(d_i d_r)}\}(n_i, n_r, 'u')$ for $u = a, e, v$

Many keys can be derived from the same exponentials for different usages

The JFKr protocol: DoS

The responder uses an authenticator against DoS

Msg 1 $i \rightarrow r : n_i, g^{d_i}$

Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$

Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$

Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

where $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, \text{IP}_i)$

$e_i = \text{Encrypt}\{k_e\}(i, id'_r, sa_i, s_i)$
 $e_r = \text{Encrypt}\{k_e\}(r, id'_i, sa'_r, s_r)$

The responder can check that the contents of msg 3 matches the contents of msg 1 & 2

$k_u = \text{Hmac}\{g^{(d_i d_r)}\}(n_i, n_r, 'u')$ for $u = a, e, v$

The JFKr protocol: Privacy

- Msg 1 $i \rightarrow r : n_i, g^{d_i}$
- Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
- Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
- Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

where $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, \text{IP}_i)$

$e_i = \text{Encrypt}\{k_e\}(\text{id}_i, \text{id}'_r, \text{sa}_i, s_i)$

$e_r = \text{Encrypt}\{k_e\}(\text{id}_r, \text{sa}'_i, s_r)$

$s_i = \text{Sign}\{i\}(n_i, n_r, g^{d_i}, g^{d_r}, p_r)$

$s_r = \text{Sign}\{r\}(g^{d_r}, n_r, g^{d_i}, n_i)$

$k_u = \text{Hmac}\{g^{(d_i d_r)}\}(n_i, n_r, \text{IP}_i, \text{IP}_r)$

Identities are always encrypted

Identities are never signed

The JFKr protocol

- Msg 1 $i \rightarrow r : n_i, g^{d_i}$
- Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
- Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
- Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

- where
- $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, IP_i)$
 - $e_i = \text{Encrypt}\{k_e\}(id_i, id'_r, sa_i, s_i)$
 - $e_r = \text{Encrypt}\{k_e\}(id_r, sa', s_r)$
 - $s_i = \text{Sign}\{i\}(n_i, n_r, g^{d_i}, g^{d_r}, p_r)$
 - $s_r = \text{Sign}\{r\}(g^{d_r}, n_r, g^{d_i}, n_i)$
 - $k_u = \text{Hmac}\{g^{(d_i d_r)}\}(n_i, n_r, 'u')$ for $u = a, e, v$

Some minor problems

Identity protection?

- Two variants with different trade-offs
 - “JFKi protects id_i against active attacks”
 - “JFKr protects id_r against active attacks and protects id_i against passive attacks”
- What is guaranteed? Does it make sense for the responder? This depends on relations between principals and roles
- Various leaks:
 - An attacker can perform traffic analysis using nonces, IP addresses, and insider knowledge (cf. private authentication)
 - A passive attacker can observe shared exponentials
 - if exponentials are re-used by a single principal, all these sessions involve the same principal
 - an active attacker (or an insider) may obtain the identity for one of these sessions

...

Identity protection in JFKr ?

Msg 1 $i \rightarrow r : n_i, g^{d_i}$
Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

where $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, \text{IP}_i)$

An attacker E can

1. Intercept message 2
2. Initiate its own session with R with the same nonce n_i and its exponential
3. Swap the two messages 2
4. Guess id_r and proceed as usual
5. Observe messages 4

The responder accepts two sessions (I,R) and (E,R) only if E 's guess is right

Fix: MAC the initiator exponential too

Non-negotiated?

- Usually, the cryptographic algorithms are negotiated: hash, encryption, certificates, compression, ...
Some algorithms are weak (legacy, legal...), or even nil.
- The protocol must (at least) authenticate the negotiation, and also relies on these operations for authentication! Cf. SSL
- “JFK is non-negotiated”: the responder demands specific algorithms, the initiator takes it or leaves it. Still...
 - If the responder demands weak algorithms, there is no guarantees at all.
 - What if the attacker modifies the responder’s demands?
 - Recent fix in JFKi: sign the algorithm demands

Caching message 3?

- “The responder caches answers to identical messages 3”
- More precisely, **the responder should answer just once for every valid token** received in a message 3.
- Otherwise, several attacks appear

Caching message 3?

Msg 1 $i \rightarrow r : n_i, g^{d_i}$
Msg 2 $r \rightarrow i : n_i, n_r, g^{d_r}, p_r, h_t$
Msg 3 $i \rightarrow r : n_i, n_r, g^{d_i}, g^{d_r}, h_t, e_i, \text{Hmac}\{k_a\}('i', e_i)$
Msg 4 $r \rightarrow i : n_i, n_r, e_r, \text{Hmac}\{k_a\}('r', e_r)$

where $h_t = \text{Hmac}\{k_t\}(g^{d_r}, n_r, n_i, \text{IP}_i)$

$e_i =$

$e_r =$

$s_i =$

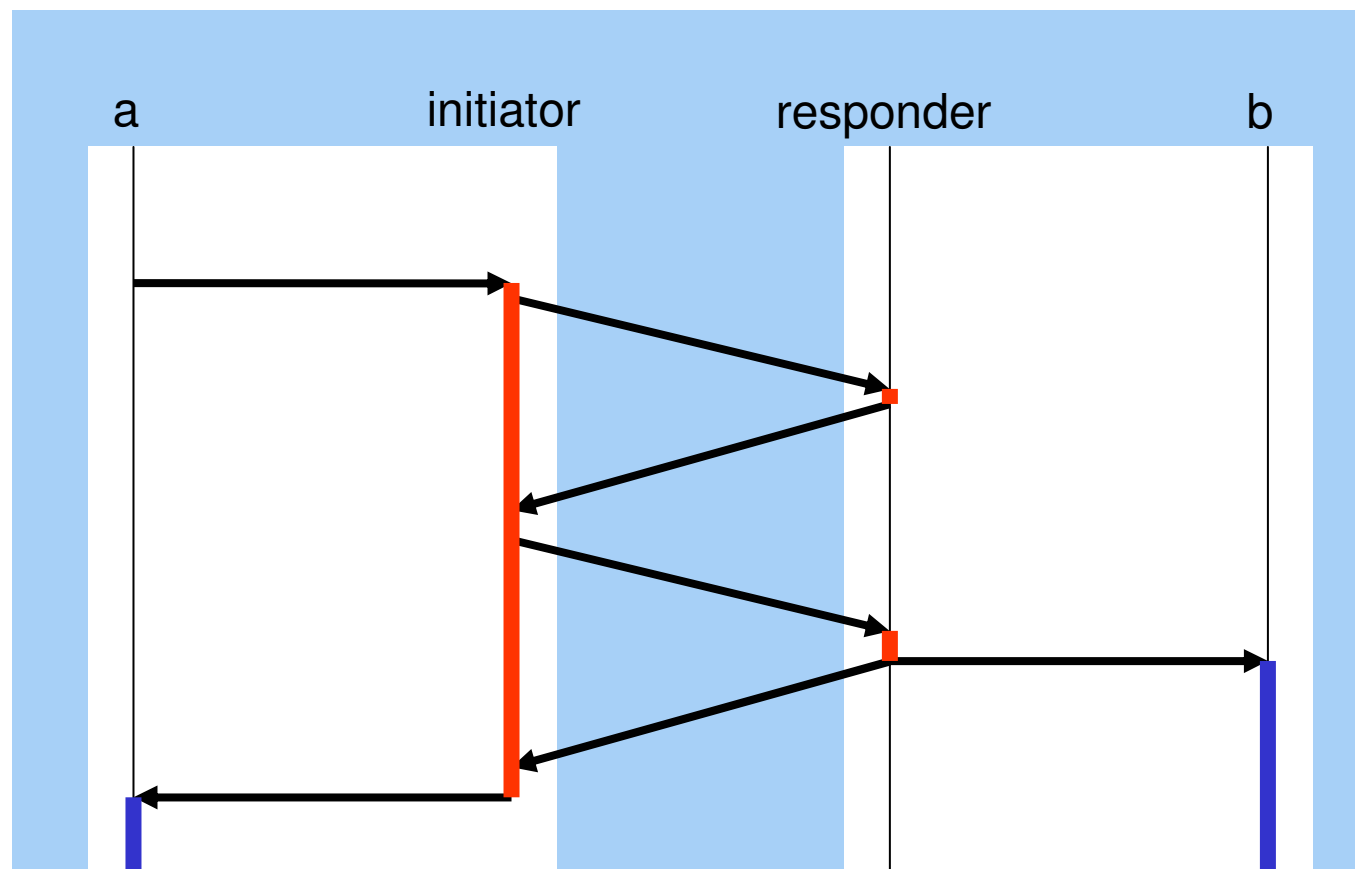

$s_r =$

$k_u =$

An active attacker could trick R into accepting sessions with the same key

An attacker E could obtain a valid message 3 and modify eg the exponential (an easy, "blind" DoS attack against R)

A model of JFK in applied pi

Public key signature

- To model **public-key signature**, we construct the public verification key from the private signing key:

$$\text{Verify}\{\text{Pk}(k), \text{Sign}\{k\}(v)\}(v) = \text{True}$$

- Using active substitutions, we can write a process that exports the public key, and keeps the signing key secret.

$$\nu s. \left(\{pk = \text{Pk}(s)\} \mid \bar{a} \langle \text{Sign}\{s\}(M) \rangle \right)$$

Control actions

- We distinguish between
 - principals (signers)
 - JFK roles: initiator, responder (exponentials)
- We provide an API between applications & JFK

Grammar for terms

$M, N ::=$	terms
x, y, z	variable
m, n, s, t	name
B^X	exponential
$\text{Pk}(K)$	public key (and identity)
$\text{S}\{K\}(T)$	public-key signature
$\text{V}\{K, S\}(D)$	public-key signature verification
$\text{H}\{K\}(T)$	keyed crypto hash function
$\text{E}\{K\}(T)$	shared-key encryption
$\text{D}\{K\}(T)$	shared-key decryption
T_e, T_a, T_v	constant tags for key derivation
$1(-, -), 2(-, -, -, -, -), \dots$	constructors for JFK messages
$F_1^1(-), \dots, F_4^2(-)$	selectors for JFK messages
$K \in S$	sets (for authorized identities)

Equations for terms

$(g^y)^z = (g^z)^y$	Diffie-Hellman exponentials
$V\{Pk(k), S\{k\}(v)\}(v) = True$	Public key signature verification
$D\{k\}(E\{k\}(v)) = v$	Shared-key decryption
$F_n^i(n(v_1, \dots, v_i, \dots)) = v_i$	Selection of message fields
$K \in \{\dots, K, \dots\} = True$	Set membership (authorization)
$RecoverKey(S\{k\}(v)) = Pk(k)$	Public key recovery *
$RecoverText(S\{k\}(v)) = v$	Signed text recovery *

JFK configuration initiator responder

$$JFK = \prod_{a \in \mathcal{L}} PK^a[I^a|R^a]$$

JFK for principals $a \in \mathcal{L}$

$$PK^a[-] = \nu a. \{id^a = Pk(a)\} \mid [-]$$

Signing key a and identity id^a

$$D_z[-] = \nu d_z. \{x_z = g^{\hat{d}_z}\} \mid [-]$$

DH secret and exponential

$$C_z = \nu h. \{h = x_{\bar{z}}^{\hat{d}_z}\} \mid \prod_{u=a,e,v} K_u$$

DH computation

$$K_u = \{k_u = H\{h\}(n_i, n_r, T_u)\}$$

derivation of key k_u

Only a specific subset of principals appear in \mathcal{L}

These are "compliant principals".

JFK configuration initiator responder

$R = \prod_{\widetilde{x_r}} \nu c_t k_t . D_r \left[\begin{array}{l} !(1(n_i, x_i)) . R_2 \mid \\ !(3(n_i, n_r, x_i, x_r, h_t, e_i, h_i)) . R_4 \end{array} \right]$	<p>responder (for a)</p>
$R_2 = \nu n_r h_t . \{h_t = H\{k_t\}(x_r, n_r, n_i)\} \mid \overline{c_t} \langle h_t \rangle \mid \langle 2(n_i, n_r, x_r, p_r, h_t) \rangle$	<p>token send message 2</p>
$R_4 = \text{if } H\{k_t\}(x_r, n_r, n_i) = h_t \text{ then}$ $c_t(h'_t) . \text{if } h'_t = h_t \text{ then}$ $\nu k_e k_a k_v . C_r \mid$ $\text{if } H\{k_a\}(T_i, e_i) = h_i \text{ then}$ $\nu id_i sa_i s_i . \{id_i, -, sa_i, s_i = D\{k_e\}(e_i)\} \mid$ $\text{if } id_i \in S_i^a \text{ then}$ $\text{if } V\{s_i, id_i\}(n_i, n_r, x_i, x_r, p_r) \text{ then}$ $\overline{\text{accept}}^a \langle id_i, sa_i, k_v \rangle .$ $\nu s_r e_r h_r .$ $\{s_r = S\{a\}(n_i, n_r, x_i, x_r)\} \mid$ $\{e_r = E\{k_e\}(id_a, sa_r, s_r)\} \mid$ $\{h_r = H\{k_a\}(T_r, e_r)\} \mid$ $\langle 4(e_r, h_r) \rangle$	<p>verify token accept token once handle message 3</p> <p>authorize authenticate complete keying</p> <p>build message 4</p> <p>send message 4</p>

Security properties ?

- Main results:
 - In any state, the protocol can establish a secure session between compliant principals
 - There are causality relations between control actions (aka authentication)
 - When both protocols are compliant, the key is secure (aka perfect forward secrecy)
- Stated independently of low-level messages
- Compliant principals are also part of the “attacker”
- Additional results:
 - Some identity protection
 - Some DOS properties
 - Some plausible deniability

Operational correctness

Basic Operational Correctness

The protocol uses internal steps:
 - low-level communications
 - tests after receiving messages

Protocol configuration with compli-

with $id_b \in S_r$. We have:

At the end of the protocol, we can use an observational equivalence to simplify the established keys.

We start from any reachable configuration of the process (past & running sessions)

Each party gets the other's identity & parameters, shared key.

We end up exactly in the original configuration !
 In particular, kv is a perfect key.

Operational correctness with eavesdropping

Let S be a running protocol configuration with compliant principals \mathcal{L} . Let $a, b \in \mathcal{L}$ and S_r be a set of terms with $id_b \in S_r$. We have:

$$\begin{array}{c}
 S \xrightarrow{\text{init}^a(S_r, id_r, sa_i)} \\
 \xrightarrow{\nu n_i. [1(n_i, x_i^a)]} \\
 \xrightarrow{\nu n_r h_t. [2(n_i, n_r, x_r^b, p_r^b, h_t)]} \\
 \xrightarrow{\nu e_i h_i. [3(n_i, n_r, x_i^a, x_r^b, h_t, e_i, h_i)]} \\
 \xrightarrow{\nu e_r h_r. [4(e_r, h_r)]} \\
 \rightarrow_4 \approx \xrightarrow{\nu k_v. \overline{\text{accept}}^b \langle id_a, sa_i, k_v \rangle} \xrightarrow{\overline{\text{connect}}^a \langle id_b, sa_r, k_v \rangle} S
 \end{array}$$

In addition, the environment can observe mostly-opaque messages, still unrelated to the session key.

where x_i^a is an exponential defined by I^a , x_r^b and p_r^b are an exponential and the preferences defined by R^b , and $n_i, n_r, h_t, e_i, h_i, e_r, h_r, k_v$ are all fresh names.

Correspondence properties

Let S_0 be an initial configuration with compliant principals \mathcal{L} and labeled transitions $S_0 \xrightarrow{\mu^*} S$ with no immediate output on any channel accept^b in S .

The actions occurring in μ have the following properties:

1. For any $\beta = \overline{\text{accept}}^b \langle id_a, sa_i, k_v \rangle$, we have $id_a \in S_i^b$.
2. For any β with $a \in \mathcal{L}$, there is a distinct $\alpha = \text{init}^a(S_r, id_r, sa_i)$ with $id_b \in S_r$.
3. For any $\gamma = \overline{\text{connect}}^a \langle id_b, sa_r, k_v \rangle$ there is a distinct $\alpha = \text{init}^a(S_r, id_r, sa_i)$ with $id_b \in S_r$.
4. For any γ with $b \in \mathcal{L}$, there is a distinct $\beta = \overline{\text{accept}}^b \langle id_a, sa_i, k_v \rangle$.
5. For any two other control actions that output a session key (either $\overline{\text{connect}}^a \langle -, -, k_v \rangle$ or $\overline{\text{accept}}^b \langle -, -, k_v \rangle$), the keys are equationally different.

Anti-DoS properties

- We characterize “round-trip communication” as a trace property:

$$\nu n_r h_t. (2(-, n_r, -, -, h_t)) \dots \langle 3(-, n_r, -, -, h_t, -, -) \rangle$$

and show an injective correspondence property from (informally) expensive responder steps to round-trips.

- The use of a token is a refinement, modelled as an equivalence
 - The basic model uses local responder state after message 1 & 2
 - The refined model uses the token instead

This is much like the parallel law for CCS

$$(!P \mid !Q) \approx !(P \mid Q)$$

Plausible deniability

- What gets signed ?
 - Authentication for an active party
 - Deniability from some (data) evidence
- Example:
 - **a** opens a session with **e** (which may not comply with JFK)
 - **e** tries to prove that **a** opened the session from his data.
 - **a** refutes **e**'s evidence by exhibiting a trace where
 - **a** complies with JFK
 - **a** never tries to open a session with **e**
 - **e** produces the same evidence

for instance, a plausible trace may be

- **a** opens a session with a compliant **b** \neq **e**
- **e** is an active attacker that impersonates **b**

Summary on JFK

- JFK is a state-of-the-art protocol, well-written but message-centric and sometimes imprecise
 - We had to interpret the spec and invent a service API
 - Writing down a precise definition for the intended properties of the protocol is difficult (and reveals problems)
- We wrote a “formal implementation” of JFKr in applied pi
- We obtained a formal counterpart for each informal claim, against a large class of active attackers (=contexts)

Questions?
