The Next 700 Data Description Languages

Kathleen Fisher
AT&T Labs Research

Yitzhak Mandelbaum, David Walker
Princeton
Review: Technical Challenges of Ad Hoc Data

• Data arrives “as is.”

• Documentation is often out-of-date or nonexistent.
  – Hijacked fields.
  – Undocumented “missing value” representations.

• Data is buggy.
  – Missing data, human error, malfunctioning machines, race conditions on log entries, “extra” data, …
  – Processing must detect relevant errors and respond in application-specific ways.
  – Errors are sometimes the most interesting portion of the data.

• Data sources often have high volume.
  – Data may not fit into main memory.
Many Data Description Languages

- **PacketTypes** (SIGCOMM ‘00)
  - Packet processing
- **DataScript** (GPCE ‘02)
  - Java jar files, ELF object files
- **Erlang Binaries** (ESOP ‘04)
  - Packet processing
- **PADS** (PLDI ‘05)
  - General ad hoc data
The Next 700 Programming Languages

The languages people use to communicate with computers differ in their intended aptitudes, towards either a particular application area, or a particular phase of computer use (high level programming, program assembly, job scheduling, etc.). They also differ in physical appearance, and more important, in logical structure. The question arises, do the idiosyncrasies reflect basic logical properties of the situation that are being catered for? Or are they accidents of history and personal background that may be obscuring fruitful developments? This question is clearly important if we are trying to predict or influence language evolution.

Continued…
The Next 700 Programming Languages, cont.

To answer it we must think in terms, not of languages, but families of languages. That is to say we must systematize their design so that a new language is a point chosen from a well-mapped space, rather than a laboriously devised construction.

— J. P. Landin

*The Next 700 Programming Languages*, 1965.
The Next 700 Data Description Languages

- What is the family of data description languages?
- How do existing languages relate to each other?
- What differences are crucial, which “accidents of history”?
- What do the existing languages mean, precisely?

To answer these questions, we introduce a semantic framework for understanding data description languages.
Contributions

• A core data description calculus (DDC)
  – Based on dependent type theory
  – Simple, orthogonal, composable types
  – Types transduce external data source to internal representation.

• Encodings of high-level DDLs in low-level DDC
Outline

• Introduction
• A Data Description “Calculus” (DDC)
• But what does DDC mean?
  – Well-kindng judgment
  – Representation, parse descriptor, and parser generation
• But what to data description languages (DDLs) mean?
  – Idealized PADS (IPADS)
  – Features from other DDLs.
• Applications of the semantics
A Data Description Calculus
Candidate DDC Primitives

- Base types parameterized by expressions (Pstring(ː|ː))
  - Type constructor constants
- Pair of fields with cascading scope (Pstruct)
  - Dependent sums
- Additional constraints (Ptypedef, Pwhere, field constraints).
  - Set types
- Alternatives (Punion, Popt)
  - Sums
- Open-ended sequences (Parray)
  - Some kind of list?
- User-defined parameterized types
  - Abstraction and application
- “Active types”: compute, absorb, and scanning
  - Built-in functions
Base Types and Sequences

- $C(e)$: base type parameterized by expression $e$.
- $\Sigma x \cdot \tau \cdot \tau'$: dependent sum describes sequence of values.
  - Variable $x$ gives name to first value in sequence.
  - Note syntactic sugar: $\tau \cdot \tau'$ if $x$ not in $\tau'$.
- Examples:

| “123hello|”      | int * string(‘|’) * char | (123, “hello”, ‘|’) |
| “3513”          | $\Sigma width:int\_fw(1). \int\_fw(width)$ | (3,513) |
| “:hello:”       | $\Sigma term:char.string(term) * char$ | (‘:’, “hello”, ‘:’) |
### Constraints

- \( \{x: \tau | e\} \): set types add constraints to the type \( \tau \) and express relationships between elements of the data.

- Examples:

<table>
<thead>
<tr>
<th>‘a’</th>
<th>( {c: \text{char} \mid c = ‘a’} ) (abbrev: ( S_c(‘a’) ))</th>
<th>inl ‘a’</th>
</tr>
</thead>
<tbody>
<tr>
<td>“101”, “82”</td>
<td>( {x: \text{int} \mid x &gt; 100} )</td>
<td>inl 101, inr 82</td>
</tr>
</tbody>
</table>
| “43|105|67” | \( \Sigma min : \text{int}.S_c(‘|’) \ast \) \\
| | \( \Sigma max : \{m: \text{int} \mid min \leq m\}.S_c(‘|’) \ast \) \\
| | \( \{mid: \text{int} \mid min \leq mid \& mid \leq max\} \) | (43, inl ‘|’, inl 105, inl ‘|’, inl 67) |
**Unions and the Empty String**

- \( \tau + \tau' \): deterministic, exclusive or
  - try \( \tau \); on failure, try \( \tau' \).
- **unit**: matches the empty string.
- **Examples**:

<table>
<thead>
<tr>
<th>“54”, “n/a”</th>
<th>int + S(_s)(“n/a”)</th>
<th>inl 54, inr (inl “n/a”)</th>
</tr>
</thead>
<tbody>
<tr>
<td>“2341”, “”</td>
<td>int + unit</td>
<td>inl 2341, inr ()</td>
</tr>
</tbody>
</table>
Array Features

• What features do we need to handle data sequences?
  – Elements
  – Separator between elements
  – Termination condition (“Are we done yet?”)
  – Terminator after sequence

• Examples:
  “192.168.1.1”
  “Harry|Ron|Hermione|Ginny;”
Bottom and Arrays

- $\tau \text{ seq}(\tau_s; e, \tau_t)$ specifies:
  - Element type $\tau$
  - Separator types $\tau_s$.
  - Termination condition $e$.
  - Terminator type $\tau_t$.

- **bottom**: reads nothing, flagging an error.

- Example: IP address.

| “192.168.1.1” | int seq(S_c(‘.’); len 4, bottom) | (4, [192, 168, 1, 1]) |
Abstraction and Application

- Can parameterize types over values: \( \lambda x. \tau \)
- Correspondingly, can apply types to values: \( \tau e \)
- Example: IP address with terminator

<table>
<thead>
<tr>
<th>none</th>
<th>( \lambda )term.int seq(S( c )(‘.’); len 4, S( c )(term))</th>
<th>none</th>
</tr>
</thead>
<tbody>
<tr>
<td>“1.2.3.4</td>
<td>”</td>
<td>IP_addr ‘</td>
</tr>
</tbody>
</table>
Absorb, Compute and Scan

- Absorb, Compute and Scan are *active* types.
  - `absorb(\(\tau\))`: consume data from source; produce nothing.
  - `compute(e:\(\sigma\))`: consume nothing; output result of computation \(e\).
  - `scan(\(\tau\))`: scan data source for type \(\tau\).

- Examples:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>“</td>
<td>”</td>
<td>`absorb(S_c(‘</td>
</tr>
</tbody>
</table>
| “10|12” | \(\Sigma\) \(width\):int.\(S_c(‘|’)\) *  
\(\Sigma\) \(length\):int.  
\(area\):compute(\(width \times length\):int) | (10,12,120) |
| “^%$!&_|” | `scan(S_c(‘|’))` | (6,inl ‘|’) |
DDC Example: Idealized Web Server Log

\[ S = \lambda c. \{ c : \text{char} \mid c = ch \} \]

\[ \text{authid}_t = S(\text{"-"}) + \text{string}(\text{" "}) \]

\[ \text{response}_t = \lambda x. \{ y : \text{int16}_\text{fw}(x) \mid 100 \leq y \text{ and } y < 600 \} \]

\[ \text{entry}_t = \]
\[ \Sigma \text{client} : \text{ip.} \quad S(\text{" "})* \]
\[ \Sigma \text{remoteid} : \text{authid}_t. \quad S(\text{" "})* \]
\[ \Sigma \text{response} : \text{response}_t 3. \]
\[ \text{compute}(\text{getdomain} \ \text{client} = \text{"edu"} : \text{bool}) \]

\[ \text{entry}_t \ \text{seq}(S(\text{"\n"}); \lambda x. \text{false}, \text{bottom}) \]

</tbody>
</table>
Semantics Overview

- Well formed DDC type: $\Gamma |- \tau : \kappa$
- Representation for type $\tau : [\tau]_{\text{rep}}$
- Parse descriptor for type $\tau : [\tau]_{\text{pd}}$
- Parsing function for type $\tau : [\tau]$
  - $[\tau] : \text{bits} \times \text{offset} \rightarrow \text{offset} \times [\tau]_{\text{rep}} \times [\tau]_{\text{pd}}$
Type Kinding

Kinding ensures types are well formed.

\[ \kappa ::= T \mid \sigma \rightarrow \kappa \]

\[
\begin{array}{c}
\frac{\Gamma \vdash \tau : \sigma \rightarrow \kappa \quad \Gamma \vdash e : \sigma}{\Gamma \vdash \tau \ e : \kappa} & \quad & \frac{\Gamma \vdash \tau : T \quad \Gamma \vdash \tau' : T}{\Gamma \vdash \tau + \tau' : \text{type}}
\end{array}
\]

\[
\begin{array}{c}
\frac{\Gamma \vdash \tau : T}{\Gamma, x:[\tau]_{\text{rep}} \ast [\tau]_{\text{pd}} \vdash e : \text{bool}} & \quad & \frac{\Gamma \vdash \{x : \tau \mid e\} : T}{\Gamma \vdash \{x : \tau \mid e\} : T}
\end{array}
\]
# Selected Representation Types

<table>
<thead>
<tr>
<th>DDC</th>
<th>Host Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>([C(e)]_{\text{rep}})</td>
<td>(\mathbb{I}(C) + \text{none})</td>
</tr>
<tr>
<td>([\Sigma x: \tau. \tau']_{\text{rep}})</td>
<td>([\tau]<em>{\text{rep}} \ast [\tau']</em>{\text{rep}})</td>
</tr>
<tr>
<td>([{x: \tau \mid e}]_{\text{rep}})</td>
<td>([\tau]<em>{\text{rep}} + [\tau]</em>{\text{rep}})</td>
</tr>
<tr>
<td>([\tau + \tau']_{\text{rep}})</td>
<td>([\tau]<em>{\text{rep}} + [\tau']</em>{\text{rep}})</td>
</tr>
<tr>
<td>([\tau \text{ seq}(\tau_s; e, \tau_t)]_{\text{rep}})</td>
<td>(\text{int} \ast ([\tau]_{\text{rep}} \text{ seq}))</td>
</tr>
<tr>
<td>([\lambda x. \tau]<em>{\text{rep}}, [\tau e]</em>{\text{rep}})</td>
<td>([\tau]_{\text{rep}})</td>
</tr>
<tr>
<td>([\text{unit}]_{\text{rep}})</td>
<td>\text{unit}</td>
</tr>
</tbody>
</table>

Note that we erase all dependencies.
## Selected Parse Descriptor Types

<table>
<thead>
<tr>
<th>DDC</th>
<th>Host Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>([C(e)]_{pd})</td>
<td>pd_hdr</td>
</tr>
<tr>
<td>([\Sigma x: \tau. \tau']_{pd})</td>
<td>pd_hdr * ([\tau]<em>{pd}) * ([\tau']</em>{pd})</td>
</tr>
<tr>
<td>([{x: \tau</td>
<td>e}]_{pd})</td>
</tr>
<tr>
<td>([\tau + \tau']_{pd})</td>
<td>pd_hdr * (([\tau]<em>{pd}) + ([\tau']</em>{pd}))</td>
</tr>
<tr>
<td>([\tau \text{ seq}(\tau_s; e, \tau_t)]_{pd})</td>
<td>pd_hdr * int * int * (([\tau]_{pd}) \text{ seq})</td>
</tr>
<tr>
<td>([\lambda x. \tau]<em>{pd}, [\tau e]</em>{pd})</td>
<td>([\tau]_{pd})</td>
</tr>
<tr>
<td>([\text{unit}]_{pd})</td>
<td>pd_hdr</td>
</tr>
</tbody>
</table>

\(pd\_hdr = \text{int} * \text{errcode} * \text{span}\)
Parsing Semantics of Types

- Semantics expressed as parsing functions written in the polymorphic $\lambda$-calculus.
  
  - $[\tau] : \text{bits} * \text{offset} \rightarrow \text{offset} * [\tau]_{\text{rep}} * [\tau]_{\text{pd}}$

- Dependent sum case:

\[
[\Sigma x : \tau. \tau'] = \\
\lambda(B, \omega).
\]

\[
\begin{align*}
\text{let } (\omega_1, r_1, p_1) &= [\tau] (B, \omega) & \text{in} \\
\text{let } x &= (r_1, p_1) & \text{in} \\
\text{let } (\omega_2, r_2, p_2) &= [\tau'] (B, \omega_1) & \text{in} \\
(\omega_2, R_\Sigma(r_1, r_2), P_\Sigma(p_1, p_2))
\end{align*}
\]
Properties of the Calculus

• **Theorem:** If $\Gamma |- \tau : \kappa$ then

  $\Gamma |- [\tau] : \text{bits} \times \text{offset} \rightarrow \text{offset} \times [\tau]_{\text{rep}} \times [\tau]_{\text{pd}}$

  “Well-formed type $\tau$ yields a parser that returns values with types corresponding to $\tau$.”

• **Theorem:** Parsers report errors accurately.
  - Errors in parse descriptor correspond to errors in representation.
  - Parsers check all semantic constraints.
Making Use of the Calculus

IPADS

\[ t ::= C(e) \mid Pfun(x:s) = t \mid t\cdot e \]
\[ \mid Pstruct\{fields\} \mid Punion\{fields\} \]
\[ \mid Pswitch e of \{alts t_{def},\} \mid Popt t \]
\[ \mid t\ Pwhere x.e \mid Palt\{fields\} \]
\[ \mid t\ Parray [t, t] \mid Pcompute e \mid Plit c \]

fields ::= | fields x : t;
alts ::= | alts e => t;
IPADS Example

authid_t = \textbf{Punion} \{ \text{unauth} : "-"; \text{id} : \textbf{Pstring}(" ")\};

response_t = \textbf{Pfun}(x:\text{int})

\textbf{Puint16}\_\textbf{FW}(x) \textbf{Pwhere} y.100 \leq y \text{ and } y < 600;

entry_t = \textbf{Pstruct} \{
    \text{client} : \textbf{Pip}; " ";
    \text{remoteid} : \text{authid_t}; " ";
    \text{response} : \text{response_t} \ 3;
    \text{academic} : \textbf{Pcompute}(\text{getdomain client} = \text{"edu"} : \text{bool});
}\;

entry_t \textbf{Parray}(\text{Peor, Peof})

124.207.15.27 - 234
12.24.20.8 kfisher 208
Example: \textbf{Popt and Plit}

\[
\begin{align*}
\text{unit} & \quad \tau_1 + \tau_2 \\
\text{t} & \Rightarrow \tau \\
\text{Popt} \quad \text{t} & \Rightarrow \tau + \text{unit} \\
\text{c} : \text{char} \\
\text{Plit} \quad \text{c} & \Rightarrow \text{scan} (\text{absorb} (\{x : \text{char} | x = \text{c}\}))
\end{align*}
\]
Example: **Pswitch**

\[ \tau + \tau' \]
\[ \lambda x. \tau \]
\[ \{ x:\tau | e \} \]

\[ t_i \Rightarrow \tau_i \quad (i = 1...n) \quad \tau_{\text{def}} \Rightarrow \tau_{\text{def}} \]

\[ \text{Pswitch } e \text{ of } \{ e_1 \Rightarrow t_1; e_2 \Rightarrow t_2; \ldots t_{\text{def}} \} \Rightarrow \]
\[ (\lambda c. \{ x:\tau_1 | c = e_1 \} + \{ x:\tau_2 | c = e_2 \} + \ldots + \tau_{\text{def}}) \; e \]

Summer School 2005
Example: $\text{Pswitch}$

$$
\begin{align*}
\tau + \tau' \\
\lambda x. \tau \\
\{x: \tau | e\}
\end{align*}
$$

$\text{Pswitch } e \text{ of } \{e_1 => t_1; e_2 => t_2; \ldots t_\text{def}\} \Rightarrow$

$$
(\lambda c. \{x: \tau_1 | c = e_1\} + \{x: \tau_2 | c = e_2\} + \ldots + \tau_\text{def}) e
$$

But this encoding isn’t exactly right, as it parses the data as each branch until it reaches the matching tag.
Encoding Conditionals

\[
\begin{align*}
\text{if } e \text{ then } t_1 \text{ else } t_2 & \Rightarrow (\{x:\text{unit} \mid !e\} + \tau_1) \ast (\{x:\text{unit} \mid e\} + \tau_2) \\
\end{align*}
\]
Pswitch Revisted

- Encode **Pswitch** as a sequence of conditionals

\[
Pswitch \ e \ \{ \hspace{1cm} \\begin{array}{l}
e_1 \Rightarrow x_1 : t_1 \\
\ldots \\
e_n \Rightarrow x_n : t_n \\
t_{\text{def}}
\end{array} \hspace{1cm} = \hspace{1cm} \left( Pfun \ (x : \text{int}) = \begin{array}{l}
\text{if } x = e_1 \text{ then } t_1 \text{ else } \\
\ldots \\
\text{if } x = e_n \text{ then } t_n \text{ else } \\
t_{\text{def}}
\end{array} \right) \ e
\]

```python
Pswitch e {
    e_1 => x_1 : t_1
    ...
    e_n => x_n : t_n
    t_{def}
}

(Pfun (x : int) =
    if x = e_1 then t_1 else
    ...
    if x = e_n then t_n else
    t_{def}) e
```
Other Features

- PacketTypes: arrays, where clauses, structures, overlays, and alternation.
- DataScript: set types (enumerations and bitmask sets), arrays, constraints, value-parameterized types, and (monotonically increasing labels).
Other Uses of the Semantics

- Bug hunting!
  - Non-termination of array parsing if no progress made.
  - Inconsistent parse descriptor construction.

- Principled extensions
  - Adding recursion (done)
  - Adding polymorphism?

- Distinguishing the essential from the accidental
  - Highlights places where PADS sacrifices safety.
  - Pomit and Pcompute: much more useful than originally thought
  - Punion: what if correct branch has an error?
Future work

• What are the set of languages recognized by the DDC?
• How does the expressive power of the DDC relate to CFGs and regular expressions?
• Add polymorphism to DDC and PADS.
Summary

- Data description languages are well-suited to describing ad hoc data.
- No one DDL will ever be right - different domains and applications will demand different languages with differing levels of expressiveness and abstraction.
- Our work defines the first semantics for data description languages.
- For more information, visit www.padsproj.org.
