Current research focused on integrating expressive logical systems and powerful theorem-proving assistants into the design, definition, implementation, and verification of programming languages and programs.
Software is now a critical component of daily infrastructure.

- computers, airplanes, mass-transit systems, power grids

Important to be able to *formally* reason about the behavior of software. Want to be able to make powerful “For all...” statements:

- For all executions of the air-traffic-control program, ...

Integration of logics and theorem-provers with programming languages is a crucial step towards wide deployment of verified software components.
The Small Picture

We won’t be formally verifying air-traffic-control programs this summer.

We will see many core ideas – specification logics, automated and interactive theorem proving, type systems, etc.

A variety of techniques and tools for reasoning at different granularities:

- at the level of individual programs
- at the level of classes of related programs
- at the level of programming-language definitions
Some basic fundamentals:

- techniques for giving precise definitions of programming languages
  - without precise definitions, we can’t reason formally about programs
- a technique for proving properties about all programs in a language
  - e.g., certain kinds of errors cannot happen in any program
Some basic fundamentals:

- Inductive definitions
  - basis for defining all kinds of logics, languages, and systems
- MinML – a little programming language
  - Syntax
  - Type system
  - Operational semantics
  - Type safety – a canonical PL proof

Acknowledgement: Many slides borrowed from a similar crash-lectures given by David Walker and Dan Grossman at previous OPLSS.
Reading and Study

  - available online (http://www.cs.cmu.edu/~rwh/plbook/book.pdf)
Inductive Definitions
Inductive Definitions

An *inductive definition* consists of:

- One or more *judgements* (i.e., assertions)
- A set of *inference rules* for deriving judgements

Example:

- Judgement is “$n \text{ nat}$”
- Inference rules are
  - “zero $\text{nat}$”
  - “if $n \text{ nat}$, then $\text{succ}(n) \text{ nat}$”
Inference rules are normally written as:

\[ J_1 \quad \cdots \quad J_n \]

\[ \frac{J_1 \quad \cdots \quad J_n}{J} \]

where \( J \) and \( J_1, \ldots, J_n \) are judgements.

\( J_1, \ldots, J_n \) are the *premises*.
\( J \) is the *conclusion*.

An inference rule with no premises is an *axiom*.
An inference rule with some premises is a *proper rule*. 
Example: the inference rules for deriving $n \text{ nat}$ are:

$$
\frac{\text{zero} \ \text{nat}}{\text{ZERO}} \quad \frac{n \ \text{nat}}{\text{SUCC}}
$$

The second rule is a *rule schema*. It denotes an infinite collection of inference rules, each one obtained by replacing the *parameter* $n$ with a concrete object.

Also, optionally label $\langle \text{ZERO}, \text{SUCC} \rangle$ rules for easy reference.
A judgement $J$ is *derivable* iff either

- there is an axiom
  
  \[
  \hline
  \hline
  J
  \hline
  \hline
  \]

- or, there is a proper rule
  
  \[
  \frac{J_1 \quad \cdots \quad J_n}{J}
  \]

such that $J_1, \ldots, J_n$ are derivable.
Derivation of Judgements

Determine whether a judgement is derivable by working backwards.

Example: the judgement $\text{succ}(\text{succ}(\text{zero})) \text{ nat}$ is derivable:

$$
\begin{align*}
\text{zero} & \quad \text{nat} \\
& \quad \text{ZERO} \\
\text{succ}(\text{zero}) & \quad \text{nat} \\
& \quad \text{SUCC} \\
\text{succ}(\text{succ}(\text{zero})) & \quad \text{nat} \\
& \quad \text{SUCC}
\end{align*}
$$
A judgement $t \text{ tree}$ asserting that $t$ is a binary tree, with rules:

$$
\begin{align*}
\text{empty tree} & \quad \text{EMPTY} \\
\text{node}(t_1, t_2) \quad \text{tree} & \quad \text{NODE}
\end{align*}
$$

The judgement $\text{node(\text{empty}, \text{node(\text{empty}, \text{empty})) tree}$ is derivable:

$$
\begin{align*}
\text{empty tree} & \quad \text{empty tree} \\
\text{empty tree} & \quad \text{node(\text{empty}, \text{empty}) tree} \\
\text{node(\text{empty}, \text{node(\text{empty}, \text{empty})) tree}
\end{align*}
$$
Rule Induction

By definition, every derivable judgement

- is the consequence of some rule,
- whose premises are derivable

Thus, the rules are an exhaustive description of the derivable judgements.

If we want to prove some property about a (derivable) judgement, then we simply consider all of the rules that may appear in the derivation.
Rule Induction

To show that every derivable judgement has a property $\mathcal{P}$, it is enough to show that

- for every rule

\[
\frac{J_1 \cdots J_n}{J}
\]

if $J_1, \ldots, J_n$ have the property $\mathcal{P}$, then $J$ has property $\mathcal{P}$.

This is the principal of *rule induction*. 
Rule Induction – $n \text{ nat}$

To prove that “If $n \text{ nat}$ (is derivable), then property $\mathcal{P}(n)$ holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of:

- $\mathcal{P}(\text{zero})$ (corresponding to $\text{zero nat ZERO}$)

- if $\mathcal{P}(n)$, then $\mathcal{P}(\text{succ}(n))$ (corresponding to $\text{succ}(n) \text{ nat SUCC}$)

This is just ordinary mathematical induction.
Rule Induction – t tree

To prove that “If t tree (is derivable), then property \( \mathcal{P}(t) \) holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of:

- \( \mathcal{P}(\text{empty}) \) (corresponding to empty tree \( \text{EMPTY} \))
- if \( \mathcal{P}(t_1) \) and \( \mathcal{P}(t_2) \), then \( \mathcal{P}(\text{node}(t_1, t_2)) \) (corresponding to node(\( t_1 \) tree, \( t_2 \) tree) \( \text{NODE} \))

This is structural induction.
Inductive Definitions
Inductive Definitions in PL
In the formal study of programming languages,

- we use inductive definitions to specify
  - abstract syntax
  - static semantics (typing)
  - dynamic semantics (evaluation)
  - other properties of programs and programming languages
- we use rule induction to prove
  - nearly everything
Concrete vs. Abstract Syntax

The *concrete syntax* of a program is a string of characters:

```
(" 3 + 2 ) * 7
```

The *abstract syntax* of a program is a tree representing the structure and the computationally relevant portion of the program:

```
+ 3 2
 ↘ ↗ ↘ 7
  * ↙ ↙  
```

Welcome and Introduction
Concrete vs. Abstract Syntax

The concrete syntax contains many elements necessary for parsing:

- parentheses
- delimiters for comments
- rules for precedence of operators

The abstract syntax is much simpler; grouping and precedence given directly by tree structure.

We work with simple abstract syntax, rather than complex concrete syntax.
We consider a little language of arithmetic expressions.

Informally, an arithmetic expression $a$ is

- a boolean value
- an if statement, with a test expression, a then-case expression, and an else-case expression
- the number zero
- the successor of an expression
- the predecessor of an expression
- a zero test of an expression
Arithmetic Expressions, Formally

The arithmetic expressions are defined by the judgement \( \text{a aexp} \).

- a boolean value

\[
\begin{align*}
\text{true aexp} & \quad \text{TRUE} \\
\text{false aexp} & \quad \text{FALSE}
\end{align*}
\]

- an if statement, with a test expression, a then-case expression, and an else-case expression

\[
\frac{a_b \text{ aexp} \quad a_t \text{ aexp} \quad a_f \text{ aexp}}{\text{IF} \quad \text{if } a_b \text{ then } a_t \text{ else } a_f \text{ aexp}}
\]

- the number zero; the successor of an expression; the predecessor of an expression; and a zero test of an expression

\[
\begin{align*}
\text{zero aexp} \\
\text{succ}(a) \text{ aexp} \\
\text{pred}(a) \text{ aexp} \\
\text{isZero}(a) \text{ aexp}
\end{align*}
\]
Defining every bit of syntax by inductive definitions is lengthy and tedious.

Syntax definitions are an especially simple form of inductive definition:
- context insensitive
- unary predicates

We use a convenient abbreviation: BNF (Backus-Naur form)
The arithmetic expressions are inductively defined by these rules:

\[
a ::= \text{true} | \text{false} | \text{if } a_b \text{ then } a_t \text{ else } a_f \mid \text{zero} | \text{succ}(a) | \text{pred}(a) | \text{isZero}(a)
\]

Implicitly defines the judgement \(a \ aexp\),
with 7 inductive rules corresponding to the 7 alternatives;

\(a\) is now a \textit{syntax metavariable}; in the following, any use of \(a\)
means an object \(a\) such that \(a \ aexp\) is derivable.
Two Functions over Arith. Exps.

We could also define via judgements:

\[
\begin{align*}
\text{consts}(\text{true}) & = \{\text{true}\} \\
\text{consts}(\text{false}) & = \{\text{false}\} \\
\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f) & = \text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f) \\
\text{consts}(\text{zero}) & = \{\text{zero}\} \\
\text{consts}(\text{succ}(a)) & = \text{consts}(a) \\
\text{consts}(\text{pred}(a)) & = \text{consts}(a) \\
\text{consts}(\text{isZero}(a)) & = \text{consts}(a)
\end{align*}
\]

\[
\begin{align*}
\text{size}(\text{true}) & = 1 \\
\text{size}(\text{false}) & = 1 \\
\text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) & = 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \\
\text{size}(\text{zero}) & = 1 \\
\text{size}(\text{succ}(a)) & = 1 + \text{size}(a) \\
\text{size}(\text{pred}(a)) & = 1 + \text{size}(a) \\
\text{size}(\text{isZero}(a)) & = 1 + \text{size}(a)
\end{align*}
\]
Lemma:
The number of distinct constants in any expression $a$ is no greater than the size of $a$.

$$|\text{consts}(a)| \leq \text{size}(a)$$

Proof?

- By rule induction on the rules for the judgement $a \text{ aexp}$
- Lingo: By induction on the structure of $a$
Lemma:
The number of distinct constants in any expression \( a \) is no greater than the size of \( a \).

\[ |\text{consts}(a)| \leq \text{size}(a) \]

Proof?

- By rule induction on the rules for the judgement \( a \text{ aexp} \)
- Lingo: By induction on the structure of \( a \)
Structural Induction on Arith. Exps.

To prove that “If a \( a \text{exp} \) (is derivable), then property \( \mathcal{P}(a) \) holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of:

- **True**: \( \mathcal{P}(\text{true}) \)
- **False**: \( \mathcal{P}(\text{false}) \)
- **If**: if \( \mathcal{P}(a_b) \) and \( \mathcal{P}(a_t) \) and \( \mathcal{P}(a_f) \), then \( \mathcal{P}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \)
- **Zero**: \( \mathcal{P}(\text{zero}) \)
- **Succ**: if \( \mathcal{P}(a) \), then \( \mathcal{P}(\text{succ}(a)) \)
- **Pred**: if \( \mathcal{P}(a) \), then \( \mathcal{P}(\text{pred}(a)) \)
- **IsZero**: if \( \mathcal{P}(a) \), then \( \mathcal{P}(\text{isZero}(a)) \)
A Lemma and Proof

Lemma:
\[ |consts(a)| \leq size(a) \]

Proof:
By induction on the structure of \( a \) (with \( \mathcal{P}(a) \equiv |consts(a)| \leq size(a) \)).

- **True**, **False**: \( \cdots \)
- **If**: \( \cdots \)
- **Zero**: \( \cdots \)
- **Succ**, **Pred**, **IsZero**: \( \cdots \)
Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

Proof:
By induction on the structure of \( a \) (with \( \mathcal{P}(a) \equiv |\text{consts}(a)| \leq \text{size}(a) \)).

- **True:**
  Show \( |\text{consts}(\text{true})| \leq \text{size}(\text{true}) \).

  \[
  |\text{consts}(\text{true})| = |\{\text{true}\}| \\
  = 1 \\
  = \text{size}(\text{true})
  \]

  (defn. of \( \text{consts} \))

  (property of \( | \cdot | \))

  (defn. of \( \text{size} \))

- **False, Zero:** Similar.
Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

Proof:
By induction on the structure of \(a\)
(with \(\mathcal{P}(a) \equiv |\text{consts}(a)| \leq \text{size}(a)\)).

- **True:**
  Show \( |\text{consts}(\text{true})| \leq \text{size}(\text{true}) \).

\[
|\text{consts}(\text{true})| = |\{\text{true}\}| = 1 = \text{size}(\text{true})
\]

  (defn. of \(\text{consts}\))
  (property of \(|\cdot|\))
  (defn. of \(\text{size}\))

- **False, Zero:** Similar.
A Lemma and Proof

Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

If:
Have \[ |\text{consts}(a_b)| \leq \text{size}(a_b) \] and \[ |\text{consts}(a_t)| \leq \text{size}(a_t) \]
and \[ |\text{consts}(a_f)| \leq \text{size}(a_f) \].
Show \[ |\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \leq \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \].

\[
|\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)|
= |\text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f)| \quad \text{(defn. of consts)}
\leq |\text{consts}(a_b)| + |\text{consts}(a_t)| + |\text{consts}(a_f)| \quad \text{(property of } | \cdot | \text{ and } \cup \text{)}
\leq \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(by induction hypothesis)}
< 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(property of } + \text{)}
= \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \quad \text{(defn. of size)}

Succ, Pred, IsZero: Similar.
A Lemma and Proof

Lemma:
|consts(a)| ≤ size(a)

If:
Have |consts(a_b)| ≤ size(a_b) and |consts(a_t)| ≤ size(a_t)
and |consts(a_f)| ≤ size(a_f).
Show |consts(if a_b then a_t else a_f)| ≤ size(if a_b then a_t else a_f).

|consts(if a_b then a_t else a_f)|
= |consts(a_b) ∪ consts(a_t) ∪ consts(a_f)| (defn. of consts)
≤ |consts(a_b)| + |consts(a_t)| + |consts(a_f)| (property of |·| and ∪)
≤ size(a_b) + size(a_t) + size(a_f) (by induction hypothesis)
< 1 + size(a_b) + size(a_t) + size(a_f) (property of +)
= size(if a_b then a_t else a_f) (defn. of size)

Succ, Pred, IsZero: Similar.
A Lemma and Proof

Lemma:
\[ | \text{consts}(a) | \leq \text{size}(a) \]

**IF:**

Have \[ | \text{consts}(a_b) | \leq \text{size}(a_b) \] and \[ | \text{consts}(a_t) | \leq \text{size}(a_t) \]
and \[ | \text{consts}(a_f) | \leq \text{size}(a_f) \].
Show \[ | \text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f) | \leq \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \].

\[
| \text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f) | \\
= | \text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f) | \quad \text{(defn. of } \text{consts}) \\
\leq | \text{consts}(a_b) | + | \text{consts}(a_t) | + | \text{consts}(a_f) | \quad \text{(property of } | \cdot | \text{ and } \cup) \\
\leq \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(by induction hypothesis)} \\
< 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(property of } +) \\
= \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \quad \text{(defn. of } \text{size})
\]

**Succ, Pred, IsZero:** Similar.
A Lemma and Proof

Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

**If:**

Have \( |\text{consts}(a_b)| \leq \text{size}(a_b) \) and \( |\text{consts}(a_t)| \leq \text{size}(a_t) \)
and \( |\text{consts}(a_f)| \leq \text{size}(a_f) \).

Show \( |\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \leq \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \).

\[
|\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \\
= |\text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f)| \quad \text{(defn. of consts)} \\
\leq |\text{consts}(a_b)| + |\text{consts}(a_t)| + |\text{consts}(a_f)| \quad \text{(property of } | \cdot | \text{ and } \cup) \\
\leq \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(by induction hypothesis)} \\
< 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(property of +)} \\
= \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \quad \text{(defn. of size)}
\]

\textbf{Succ, Pred, IsZero: Similar.}
A Lemma and Proof

Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

- **If:**
  
  Have \(|\text{consts}(a_b)| \leq \text{size}(a_b)\) and \(|\text{consts}(a_t)| \leq \text{size}(a_t)\)
  
  and \(|\text{consts}(a_f)| \leq \text{size}(a_f)\).
  
  Show \(|\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \leq \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f)\).

\[
\begin{align*}
|\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \\
&= |\text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f)| \quad \text{(defn. of const)} \\
&\leq |\text{consts}(a_b)| + |\text{consts}(a_t)| + |\text{consts}(a_f)| \quad \text{(property of } | \cdot | \text{ and } \cup) \\
&\leq \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(by induction hypothesis)} \\
&< 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \quad \text{(property of +)} \\
&= \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \quad \text{(defn. of size)}
\end{align*}
\]

- **Succ, Pred, IsZero:** Similar.
A Lemma and Proof

Lemma:
\[ |\text{consts}(a)| \leq \text{size}(a) \]

**If:**

Have \[ |\text{consts}(a_b)| \leq \text{size}(a_b) \] and \[ |\text{consts}(a_t)| \leq \text{size}(a_t) \]
and \[ |\text{consts}(a_f)| \leq \text{size}(a_f) \].
Show \[ |\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \leq \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f) \].

\[
|\text{consts}(\text{if } a_b \text{ then } a_t \text{ else } a_f)| \\
= |\text{consts}(a_b) \cup \text{consts}(a_t) \cup \text{consts}(a_f)| \\
\leq |\text{consts}(a_b)| + |\text{consts}(a_t)| + |\text{consts}(a_f)| \\
\leq \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \\
< 1 + \text{size}(a_b) + \text{size}(a_t) + \text{size}(a_f) \\
= \text{size}(\text{if } a_b \text{ then } a_t \text{ else } a_f)
\]

**Succ, Pred, IsZero:** Similar.
**What is a Proof?**

A proof is an easily-checked justification of a proposition (e.g., a theorem).

Different people have different ideas about what “easily-checked” means.

The more formal a proof, the more “easily-checked”.
- Formal enough, it can be checked by a computer.
- *Many, many* examples to come!

Next up: a canonical proof in PL – type safety.
MinML
Study MinML, a tiny fragment of ML

- integer and booleans
- recursive functions

Rich enough to be Turing complete, but small enough to support a thorough analysis of its properties.
Defining MinML

What does it mean to define a programming language?

- Define the syntax of the programming language
  - what objects can be considered programs
- Define the semantics of the programming language
  - what does a program mean
  - how does a program execute (operational semantics)
  - what guarantees hold of program execution (static semantics)
MinML
Abstract Syntax of MinML
Abstract Syntax

The expressions of MinML are inductively defined by these rules:

Numbers \( n ::= \cdots | -2 | -1 | 0 | 1 | 2 | \cdots \)

Expressions \( e ::= n | e_1 + e_2 | e_1 = e_2 | \cdots | true | false | if e_b then e_t else e_f | \chi | \text{fun } f(\chi) > e | e_f e_a \)

- \( \chi \) and \( f \) range over a set of variables
Bound and Free Variables

In the expression \( \text{fun } f(x) \triangleright e \), the variables \( f \) and \( x \) are *bound*.

- Example: \( x \) is bound in \( \text{fun } f(x) \triangleright x \).
- Example: \( x \) is bound in \( \text{fun } f(x) \triangleright \text{fun } g(y) \triangleright \text{fun } h(z) \triangleright x(y,z) \).
- Lingo: the *scope* of the variables \( f \) and \( x \) is the expression \( e \).

Variables that are not bound are *free*.

- Example: \( x \) is free in \( x y \).
- Example: \( x \) is free in \( \text{fun } g(y) \triangleright x y \).

- Example: In \( (\text{fun } f(x) \triangleright x) x \),
  the first occurrence of \( x \) is bound and
  the second occurrence of \( x \) is free.

An expression with no free variables is *closed*. 
We use *standard conventions* involving bound variables:

- Expressions differing only in names of bound variables are equivalent:
  - Example: \((\text{fun } f(x) \triangleright x + 3) \equiv (\text{fun } g(y) \triangleright y + 3)\).
  - Lingo: we work with expressions “up to alpha-conversion”.

- Can always *pick* bound variables to avoid clashes with other variables.
  - Lingo: we use the “Barendregt convention”.
The *capture-avoiding substitution* $e[e'/\chi]$ replaces all free occurrences of $\chi$ with $e'$ in $e$.

- Example: $(\text{fun } f(\chi) \triangleright \chi + y)[3/y] = (\text{fun } f(\chi) \triangleright \chi + 3)$.

Warning! Naïve substitution can “capture” free variables.
Rename bound variables during substitution to avoid “capture”:

- Example: $(\text{fun } f(\chi) \triangleright \chi + y)[\chi/y] = (\text{fun } f(z) \triangleright z + \chi)$. 
I have not *formally* defined any of these notions.

Intended meanings are intuitively obvious, but surprisingly tricky to define/use formally.

- Much more from Harper, Urban, and Weirich.
MinML
Static Semantics of MinML
The *static semantics* (or *type system*) imposes context-sensitive restrictions on programs.

- Distinguishes *well-typed* from *ill-typed* expressions.
- Well-typed programs (definitely) have well-defined behavior; ill-typed programs (may) have ill-defined behavior.
- In a well-typed program, every expression has a type.
Abstract Syntax for Types

The types of MinML are inductively defined by these rules:

\[
\text{Types} \quad t ::= \text{num} \mid \text{bool} \mid t_d \to t_r
\]

We redefine the expressions of MinML to annotate recursive functions with the types of their domain and range.

\[
\text{Expressions} \quad e ::= \cdots \mid \text{fun} f(\chi : t_d) : t_r \triangleright e \mid \cdots
\]
A typing judgement, or typing assertion, is a triple $\Gamma \vdash e : t$

- a type context $\Gamma$ that assigns types to a set of variables,
- an expression $e$ whose free variables are given by $\Gamma$, and
- a type $t$ for the expression $e$ in context $\Gamma$.

Read: “In context $\Gamma$, expression $e$ has type $t$.”

A type context is a finite function $\Gamma : Vars \to Types$.

We write $\Gamma, \chi : t$ for the function $\Gamma'$ defined as follows:

\[
\begin{align*}
\Gamma'(\chi) &= t \\
\Gamma'(y) &= \Gamma(y) \quad \text{if } y \neq \chi
\end{align*}
\]
A variable has whatever type $\Gamma$ assigns to it:

$$\Gamma(x) = t \quad \frac{}{\Gamma \vdash x : t} \text{VAR}$$

The constants have the obvious types:

$$\Gamma \vdash n : \text{num} \quad \text{NUM} \quad \Gamma \vdash \text{true} : \text{bool} \quad \text{TRUE} \quad \Gamma \vdash \text{false} : \text{bool} \quad \text{FALSE}$$
The numeric operations have the expected typing rules:

\[
\begin{align*}
\Gamma \vdash e_1 : \text{num} & \quad \Gamma \vdash e_2 : \text{num} \\
\Gamma \vdash e_1 + e_2 : \text{num} & & \text{ADD}
\end{align*}
\]

\[
\begin{align*}
\Gamma \vdash e_1 : \text{num} & \quad \Gamma \vdash e_2 : \text{num} \\
\Gamma \vdash e_1 = e_2 : \text{bool} & & \text{EQ}
\end{align*}
\]
Typing Rules

Conditionals:

\[\Gamma \vdash e_b : \text{bool} \quad \Gamma \vdash e_t : t \quad \Gamma \vdash e_2 : t\]
\[\Gamma \vdash \text{if } e_b \text{ then } e_t \text{ else } e_f : t\]

- Both “branches” of a conditional must have the same type!
- Intuitively, we can’t predict the outcome of the test, so we must insist that both results have the same type.
- Otherwise, we could not assign a unique type to the conditional.
Functions may only be applied to arguments in their domain, returning results in their range.
Typing Rules

Recursive functions:

\[
\begin{align*}
\Gamma, f : t_d \rightarrow t_r, \chi : t_d & \vdash e : t_r \\
\Gamma & \vdash \text{fun} f(\chi : t_d) : t_r \triangleright e : t_d \rightarrow t_r
\end{align*}
\]

\text{FUN}

- We assume that \( \{f, \chi\} \cap \text{dom}(\Gamma) = \emptyset \).
  This is always possible by our conventions on bound variables.
- The typing rule for a recursive function is tricky!
- We assume that
  - the function has the specified domain and range types, and
  - the argument has the specified domain type
- We verify that the body has the range type under these assumptions.
- If the assumptions are consistent,
  then the function really has the specified domain and range types.
Well-Typed and Ill-Typed Expressions

An expression \( e \) is \textit{well-typed} in a context \( \Gamma \) iff there exists a type \( t \) such that \( \Gamma \vdash e : t \) (is derivable).

If there is no type \( t \) such that \( \Gamma \vdash e : t \) (is derivable), then expression \( e \) is \textit{ill-typed} in context \( \Gamma \).
Typing Example

Consider the following expression $e_{\text{fact}}$:

$$
\text{fun } f(n : \text{num}) : \text{num} \triangleright \\
\quad \text{if } n = 0 \text{ then } 1 \text{ else } n \ast (f(n - 1))
$$

Lemma: The expression $e_{\text{fact}}$ has the type $\text{num} \rightarrow \text{num}$.

To prove this, we must show that $\emptyset \vdash e_{\text{fact}} : \text{num} \rightarrow \text{num}$. 
Typing Example

\[ \begin{align*}
\Gamma(n) &= \text{num} \\
\Gamma(f) &= \text{num} \rightarrow \text{num} \\
\Gamma \vdash n : \text{num} \\
\Gamma \vdash f : \text{num} \rightarrow \text{num} \\
\Gamma \vdash n - 1 : \text{num} \\
\Gamma \vdash f(n - 1) : \text{num} \\
\Omega &= \Gamma \vdash n \ast (f(n - 1)) : \text{num}
\end{align*} \]

\[ \begin{align*}
\Gamma(n) &= \text{num} \\
\Gamma \vdash n : \text{num} \\
\Gamma \vdash 0 : \text{num} \\
\Gamma \vdash n = 0 : \text{bool} \\
\Gamma \vdash 1 : \text{num} \\
\Omega &= \Gamma \vdash n \ast (f(n - 1)) : \text{num}
\end{align*} \]

\[ \Gamma \vdash \text{if } n = 0 \text{ then } 1 \text{ else } n \ast (f(n - 1)) : \text{num} \]

\[ \emptyset \vdash \text{fun } f(n : \text{num}) : \text{num} \triangleright \text{if } n = 0 \text{ then } 1 \text{ else } n \ast (f(n - 1)) : \text{num} \rightarrow \text{num} \]

- where \( \Gamma = \emptyset, f : \text{num} \rightarrow \text{num}, n : \text{num} \)
Typing Example

The typing rules tell us exactly when a program is well-typed and when it is ill-typed.

A type checker is a program that decides:

Given \( \Gamma, e, \) and \( t, \)

does there exist a derivation \( \Gamma \vdash e : t \)

according to the typing rules?
Type Checking

How does the type checker find typing proofs?

Fact: the typing rules are *syntax directed*
  - there is exactly one rule per expression form.

Therefore, the type checker can *invert* the typing rules and work backwards from the expression to build the proof.
  - Example: if the expression is a function, then the only possible proof applies the function typing rule.
  - So, use that rule and check the body.
The static semantics of MinML is specified by an inductive definition of the typing judgement $\Gamma \vdash e : t$.

\[
\emptyset = \frac{}{\Gamma \vdash e : t}
\]

Properties of the type system may be proved by induction (on typing derivations).
Induction on Typing Derivations

To prove that “If $\Gamma \vdash e : t$, then property $\mathcal{P}(\Gamma, e, t)$ holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of:

- $\mathcal{P}(\Gamma, n, \text{num})$
- if $\mathcal{P}(\Gamma, e_1, \text{num})$ and $\mathcal{P}(\Gamma, e_2, \text{num})$, then $\mathcal{P}(\Gamma, e_1 + e_2, \text{num})$
- if $\mathcal{P}(\Gamma, e_1, \text{num})$ and $\mathcal{P}(\Gamma, e_2, \text{num})$, then $\mathcal{P}(\Gamma, e_1 = e_2, \text{bool})$
- $\mathcal{P}(\Gamma, \text{true}, \text{bool})$
- $\mathcal{P}(\Gamma, \text{false}, \text{bool})$
- if $\mathcal{P}(\Gamma, e_b, \text{bool})$ and $\mathcal{P}(\Gamma, e_t, t)$ and $\mathcal{P}(\Gamma, e_f, t)$, then $\mathcal{P}(\Gamma, \text{if } e_b \text{ then } e_t \text{ else } e_f, t)$
- if $\Gamma(\chi) = t$, then $\mathcal{P}(\Gamma, \chi, t)$
- if $\mathcal{P}(\Gamma, f : t_d \rightarrow t_r, \chi : t_d, e, t_r)$, then $\mathcal{P}(\Gamma, \text{fun } f(\chi : t_d) : t_r \triangleright e, t_d \rightarrow t_r)$
- if $\mathcal{P}(\Gamma, e_f, t_d \rightarrow t_r)$ and $\mathcal{P}(\Gamma, e_a, t_d)$, then $\mathcal{P}(\Gamma, e_f e_a, t_r)$
Properties of Typing

Lemma (Inversion):

- if $\Gamma \vdash n : t$, then $t = \text{num}$.
- if $\Gamma \vdash e_1 + e_2 : t$, then $\Gamma \vdash e_1 : \text{num}$ and $\Gamma \vdash e_2 : \text{num}$ and $t = \text{num}$.
- if $\Gamma \vdash e_1 = e_2 : t$, then $\Gamma \vdash e_1 : \text{num}$ and $\Gamma \vdash e_2 : \text{num}$ and $t = \text{bool}$.
- if $\Gamma \vdash \text{true} : t$, then $t = \text{bool}$.
- if $\Gamma \vdash \text{false} : t$, then $t = \text{bool}$.
- if $\Gamma \vdash \text{if } e_b \text{ then } e_t \text{ else } e_f : t$, then $\Gamma \vdash e_b : \text{bool}$ and $\Gamma \vdash e_t : t$ and $\Gamma \vdash e_f : t$.
- if $\Gamma \vdash \chi : t$, then $\Gamma(\chi) = t$.
- if $\Gamma \vdash \text{fun } f(\chi : t_d) : t_r \triangleright e : t$, then $\Gamma, f : t_d \rightarrow t_r, \chi : t_d \vdash e : t_r$ and $t = t_d \rightarrow t_r$.
- if $\Gamma \vdash e_f e_a : t$, then $\Gamma \vdash e_f : t_d \rightarrow t_r$ and $\Gamma \vdash e_a : t_d$ and $t = t_r$.

Proof:
By induction on the typing rules.
Properties of Typing

Lemma (Inversion; $n$):

- if $\Gamma \vdash n : t$, then $t = \text{num}$. 
Lemma (Inversion; \( n \)):

Lemma (Weakening):
If $\Gamma \vdash e : t$ and $\text{dom}(\Gamma) \subseteq \text{dom}(\Gamma')$, then $\Gamma' \vdash e : t$.

Proof:
By induction on the typing derivation $\Gamma \vdash e : t$.

Intuition:
Extra “junk” in the context doesn’t matter.
Lemma (Weakening):
If $\Gamma \vdash e : t$ and $\text{dom}(\Gamma) \subseteq \text{dom}(\Gamma')$, then $\Gamma' \vdash e : t$.

Proof:
By induction on the typing derivation $\Gamma \vdash e : t$.

Intuition:
Extra “junk” in the context doesn’t matter.
Properties of Typing

Lemma (Weakening):
If $\Gamma \vdash e : t$ and $\text{dom}(\Gamma) \subseteq \text{dom}(\Gamma')$, then $\Gamma' \vdash e : t$.

Proof:
By induction on the typing derivation $\Gamma \vdash e : t$.

Intuition:
Extra “junk” in the context doesn’t matter.
Properties of Typing

Lemma (Substitution):

If $\Gamma \vdash e : t$ and $\Gamma(\chi) = t_x$ and $\Gamma \setminus \chi \vdash e_{\chi} : t_x$, then $\Gamma \setminus \chi \vdash e[e_{\chi}/\chi] : t$.

Proof:

By induction on the typing derivation $\Gamma, \chi : t_x \vdash e : t$ (using Weakening).

Intuition:

$$\begin{align*}
\Gamma'(\chi) &= t_x \\
\Gamma' &\vdash x : t_x \\
\vdots &\vdots \\
\Gamma &\vdash e : t \\
\Gamma''(\chi) &= t_x \\
\Gamma'' &\vdash x : t_x \\
\vdots &\vdots \\
\Gamma \setminus \chi &\vdash e_{\chi} : t_x \\
\Gamma'' &\vdash e_{\chi} : t_x \\
\vdots &\vdots \\
\Gamma \setminus \chi &\vdash e[e_{\chi}/\chi] : t
\end{align*}$$
Lemma (Substitution): If $\Gamma \vdash e : t$ and $\Gamma(\chi) = t_x$ and $\Gamma \setminus \chi \vdash e_x : t_x$, then $\Gamma \setminus \chi \vdash e[e_x/\chi] : t$.

Proof: By induction on the typing derivation $\Gamma, \chi : t_x \vdash e : t$ (using Weakening).

Intuition:

\[
\begin{align*}
\Gamma'(\chi) &= t_x & \Gamma''(\chi) &= t_x \\
\Gamma' \vdash \chi : t_x & & \Gamma'' \vdash \chi : t_x \\
\vdots & & \vdots \\
\Gamma \vdash e : t & \quad \Rightarrow & \quad \Gamma' \setminus \chi \vdash e_x : t_x & & \Gamma'' \setminus \chi \vdash e_x : t_x \\
\vdots & & \vdots & & \vdots \\
\Gamma \setminus \chi \vdash e[e_x/\chi] : t
\end{align*}
\]
Properties of Typing

Lemma (Substitution):
If $\Gamma \vdash e : t$ and $\Gamma(x) = t_x$ and $\Gamma \setminus x \vdash e_x : t_x$,
then $\Gamma \setminus x \vdash e[e_x/x] : t$.

Proof:
By induction on the typing derivation $\Gamma, x : t_x \vdash e : t$ (using Weakening).

Intuition:
\[
\frac{\Gamma'(x) = t_x \quad \Gamma''(x) = t_x}{\Gamma' \vdash x : t_x \quad \Gamma'' \vdash x : t_x}
\quad \frac{\Gamma' \setminus x \vdash e_x : t_x \quad \Gamma'' \setminus x \vdash e_x : t_x}{\vdots \quad \vdots}
\quad \frac{\Gamma \vdash e : t}{\Gamma \setminus x \vdash e[e_x/x] : t}
\]

\[
\frac{\Gamma'(x) = t_x \quad \Gamma''(x) = t_x}{\Gamma' \vdash x : t_x \quad \Gamma'' \vdash x : t_x}
\quad \frac{\Gamma' \setminus x \vdash e_x : t_x \quad \Gamma'' \setminus x \vdash e_x : t_x}{\vdots \quad \vdots}
\quad \frac{\Gamma \vdash e : t}{\Gamma \setminus x \vdash e[e_x/x] : t}
\]

\[
\frac{\Gamma'(x) = t_x \quad \Gamma''(x) = t_x}{\Gamma' \vdash x : t_x \quad \Gamma'' \vdash x : t_x}
\quad \frac{\Gamma' \setminus x \vdash e_x : t_x \quad \Gamma'' \setminus x \vdash e_x : t_x}{\vdots \quad \vdots}
\quad \frac{\Gamma \vdash e : t}{\Gamma \setminus x \vdash e[e_x/x] : t}
\]

\[
\frac{\Gamma'(x) = t_x \quad \Gamma''(x) = t_x}{\Gamma' \vdash x : t_x \quad \Gamma'' \vdash x : t_x}
\quad \frac{\Gamma' \setminus x \vdash e_x : t_x \quad \Gamma'' \setminus x \vdash e_x : t_x}{\vdots \quad \vdots}
\quad \frac{\Gamma \vdash e : t}{\Gamma \setminus x \vdash e[e_x/x] : t}
\]

\[
\frac{\Gamma'(x) = t_x \quad \Gamma''(x) = t_x}{\Gamma' \vdash x : t_x \quad \Gamma'' \vdash x : t_x}
\quad \frac{\Gamma' \setminus x \vdash e_x : t_x \quad \Gamma'' \setminus x \vdash e_x : t_x}{\vdots \quad \vdots}
\quad \frac{\Gamma \vdash e : t}{\Gamma \setminus x \vdash e[e_x/x] : t}
\]
MinML
Dynamic Semantics of MinML
Dynamic Semantics

Describes how a program executes.

A number of different ways to specify:

- **Denotational**: Compile into a language (e.g., mathematics) with a well understood meaning.

- **Axiomatic**: Given some (logical) preconditions $P$, state the postconditions $Q$ that hold after execution:
  - $\{P\} \ e \ {Q}$ – Hoare logic

- **Operational**: Define execution by rewriting the program step-by-step.
  - small-step
  - large-step
  - contextual

In this lecture, we give a small-step operational semantics.
Evaluation Judgements

An evaluation judgement is a tuple $e \rightarrow e'$

- an expression $e$ to evaluate, and
- an expression $e'$ to which $e$ evaluates (in one step).

Read: “The expression $e$ steps to the expression $e'$.”

A step consists of execution of a single “instruction”.

Rules determine which “instruction” to execute next.

There are no steps from $values$. 
The values of MinML are defined by these rules:

$$
\text{Values } v ::= n \mid \text{true} \mid \text{false} \mid \chi \mid \text{fun } f(\chi : t_d) : t_r \triangle e
$$

Technically, the rules for the values of MinML define a judgement representing a *predicate* on expressions of MinML.

Using the metavariable $v$ is more convenient than (explicitly) defining the judgement $e \text{ isVal}$ and adding $\cdots \land e \text{ isVal}$ to rules and theorems.
Evaluation Rules

First, we define the primitive rules of MinML (the “instructions”).

- Primitive operations on numbers.
- Conditional branch when the test is either true or false.
- Application of a recursive function to an argument value.

Second, we specify the next “instruction” to execute by search rules. These rules specify the order of evaluation for MinML expressions.

- Left-to-right evaluation order.
The numeric operations have the expected primitive evaluation rules:

\[
\frac{n_1 + n_2 = n}{n_1 + n_2 \rightarrow n} \quad \text{ADD}
\]

\[
\frac{n_1 = n_2}{n_1 = n_2 \rightarrow \text{true}} \quad \text{EQT}
\]

\[
\frac{n_1 \neq n_2}{n_1 = n_2 \rightarrow \text{false}} \quad \text{EQF}
\]
Evaluation Rules – Primitive

Conditionals:

\[
\text{if true then } e_t \text{ else } e_f \rightarrow e_t \quad \text{IFT}
\]

\[
\text{if false then } e_t \text{ else } e_f \rightarrow e_f \quad \text{IFF}
\]
Applications:

\[(\text{fun } f(\chi : t_d) : t_r \triangleright e) \nu_a \longrightarrow e[(\text{fun } f(\chi : t_d) : t_r \triangleright e)/f][\nu_a/\chi]^{\text{APP}}\]

- Substitute the entire recursive function expression for \(f\) in \(e\).
The numeric operations are evaluated left-to-right:

\[
\begin{align*}
&\frac{e_1 \rightarrow e_1'}{e_1 + e_2 \rightarrow e_1' + e_2} \quad \text{ADDL} \\
&\frac{e_1 \rightarrow e_1'}{e_1 = e_2 \rightarrow e_1' = e_2} \quad \text{EQL} \\
&\frac{e_2 \rightarrow e_2'}{v_1 + e_2 \rightarrow v_1 + e_2'} \quad \text{ADDR} \\
&\frac{e_2 \rightarrow e_2'}{v_1 = e_2 \rightarrow v_1 = e_2'} \quad \text{EQR}
\end{align*}
\]
Conditionals search for the next “instruction” in the test expression:

\[ e_b \rightarrow e'_b \]

\[ \text{if } e_b \text{ then } e_t \text{ else } e_f \rightarrow \text{if } e'_b \text{ then } e_t \text{ else } e_f \]
Applications are evaluated left-to-right:

\[
\begin{align*}
  e_f & \longrightarrow e'_f \\
  e_f e_a & \longrightarrow e'_f e_a \\
  v_f & \longrightarrow v'_f \\
  e_a & \longrightarrow e'_a \\
  v_f e_a & \longrightarrow v'_f e'_a
\end{align*}
\]

\[\text{APPF} \quad \text{APPF} \quad \text{APPF}\]
The judgement $e \xrightarrow{*} e''$ is inductively defined by the following rules:

\[
\begin{align*}
\text{Refl} & : & e & \xrightarrow{*} e \\
\text{Step} & : & e \xrightarrow{e'} & e' \xrightarrow{*} e'' \\
\end{align*}
\]

Read: “The expression $e$ multi-steps to the expression $e''$.”

Intuitively, $e \xrightarrow{*} e''$ iff $e \equiv e_0 \rightarrow e_1 \rightarrow \cdots \rightarrow e_n \equiv e''$ for $n \geq 0$. 
Consider the following expression/value $v_{\text{fact}}$:

\[
\text{fun } f(n : \text{num}) : \text{num} \triangleright \\
\quad \text{if } n = 0 \text{ then } 1 \text{ else } n \ast (f(n - 1))
\]

One step of evaluation:

\[
v_{\text{fact}} \ 3 \quad \longrightarrow \quad \text{if } 3 = 0 \text{ then } 1 \text{ else } 3 \ast (v_{\text{fact}}(3 - 1))
\]

We have substituted $v_{\text{fact}}$ for $f$ and 3 for $\chi$ in the body of the function.
Evaluation Example

\[ v_{\text{fact}} 3 \rightarrow \text{if } 3 = 0 \text{ then } 1 \text{ else } 3 \ast (v_{\text{fact}} (3 - 1)) \]
\[ \rightarrow \text{if false then } 1 \text{ else } 3 \ast (v_{\text{fact}} (3 - 1)) \]
\[ \rightarrow 3 \ast (v_{\text{fact}} (3 - 1)) \]
\[ \rightarrow 3 \ast (v_{\text{fact}} 2) \]
\[ \rightarrow 3 \ast (\text{if } 2 = 0 \text{ then } 1 \text{ else } 2 \ast (v_{\text{fact}} (2 - 1))) \]
\[ \rightarrow \ldots \]
\[ \rightarrow 3 \ast (2 \ast (1 \ast 1)) \]
\[ \rightarrow 3 \ast (2 \ast 1) \]
\[ \rightarrow 3 \ast 2 \]
\[ \rightarrow 6 \]

where

\[ v_{\text{fact}} = \text{fun } f(n : \text{num}) : \text{num} \rightarrow \text{if } n = 0 \text{ then } 1 \text{ else } n \ast (f(n - 1)) \]
The dynamic semantics of MinML is specified by inductive definitions of the evaluation judgements $e \rightarrow e'$ and $e \rightarrow^* e''$.

\[
\begin{array}{c}
\vdots \\
\mathcal{D} = \frac{e \rightarrow e'}{e}
\end{array}
\]

Properties of evaluation may be proved by induction (on evaluation derivations).
Induction on Evaluation Derivations

To prove that “If \( e \rightarrow e' \), then property \( \mathcal{P}(e, e') \) holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of (primitive rules):

- if \( n_1 + n_2 = n \), then \( \mathcal{P}(n_1 + n_2, n) \)
- if \( n_1 = n_2 \), then \( \mathcal{P}(n_1 = n_2, \text{true}) \)
- if \( n_1 \neq n_2 \), then \( \mathcal{P}(n_1 = n_2, \text{false}) \)
- \( \mathcal{P}(\text{if true then } e_t \text{ else } e_f, e_t) \)
- \( \mathcal{P}(\text{if false then } e_t \text{ else } e_f, e_f) \)
- \( \mathcal{P}(\text{fun } f(\chi : t_d) : t_r \triangleright e) \triangleright v_a, e[(\text{fun } f(\chi : t_d) : t_r \triangleright e)/f][v_a/\chi]) \)
To prove that “If $e \rightarrow e'$, then property $\mathcal{P}(e, e')$ holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of (search rules):

- if $\mathcal{P}(e_1, e'_1)$, then $\mathcal{P}(e_1 + e_2, e'_1 + e_2)$
- if $\mathcal{P}(e_2, e'_2)$, then $\mathcal{P}(v_1 + e_2, v_1 + e'_2)$
- if $\mathcal{P}(e_1, e'_1)$, then $\mathcal{P}(e_1 = e_2, e'_1 = e_2)$
- if $\mathcal{P}(e_2, e'_2)$, then $\mathcal{P}(v_1 = e_2, v_1 = e'_2)$
- if $\mathcal{P}(e_b, e'_b)$, then $\mathcal{P}(\text{if } e_b \text{ then } e_t \text{ else } e_f, \text{if } e'_b \text{ then } e_t \text{ else } e_f)$
- if $\mathcal{P}(e_f, e'_f)$, then $\mathcal{P}(e_f e_a, e'_f e_a)$
- if $\mathcal{P}(e_a, e'_a)$, then $\mathcal{P}(v_f e_a, v'_f e'_a)$
To prove that “If $e \rightarrow^* e''$, then property $\mathcal{Q}(e, e'')$ holds”, it is enough to show that the property holds for the conclusion of each rule given that it holds for each of the premises of the rule.

That is it is enough to show each of:

- $\mathcal{Q}(e, e)$
- if $e \rightarrow e'$ and $\mathcal{Q}(e', e'')$, then $\mathcal{Q}(e, e'')$
  - Often this involves proving (by induction) some property $\mathcal{P}$ of the single-step evaluation derivation.
Properties of Evaluation

Lemma (Values Irreducible):
There is no $e'$ such that $v \rightarrow e'$.

Proof:
By induction on the evaluation rules.

Rephrase the lemma as “If $e \rightarrow e'$, then $\forall v. e \neq v$.”
By induction on the evaluation derivation $e \rightarrow e'$.

Lingo: by inspection of the evaluation rules.
Properties of Evaluation

Lemma (Determinacy):
For every $e$ there exists at most one $e'$ such that $e \rightarrow e'$.

Proof:
By induction on the structure of $e$ (using Values Irreducible)

Lemma (Determinacy of Values):
For every $e$ there exists at most one $v''$ such that $e \rightarrow^* v''$.

Proof:
By induction on the derivation of $e \rightarrow^* v''$ (using Determinacy).
Not every irreducible expression is a value!
- if 7 then 1 else 2 does not reduce
- true + false does not reduce
- true 1 does not reduce

If an expression is not a value and it doesn’t reduce, then its meaning is ill-defined.
- Anything can happen next

An expression $e$ that is not a value and for which there exists no $e'$ such that $e \rightarrow e'$ is stuck.
The dynamic semantics of MinML is specified by inductive definitions of the evaluation judgements $e \rightarrow e'$ and $e \rightarrow^* e''$.

\[
\begin{align*}
\mathcal{D} & = e \rightarrow e' \\
\vdots \\
\end{align*}
\]

Evaluation is deterministic.

Evaluation can get stuck ... if expressions are not well-typed.
A type system predicts something about the execution of a program.

\[
\emptyset \vdash e : \text{num} \to \text{num}
\]

- the expression \(e\) will evaluate to a function value that takes an integer argument and returns an integer result, or does not terminate
- the expression \(e\) will not get stuck during evaluation
Type Safety

Type safety formalizes a coherence between the static and dynamic semantics of a programming language.

- The static semantics makes predictions about the execution behavior.
- The dynamic semantics must comply with those predictions.

The validity of the predictions guarantees that certain errors never occur. The kinds of error vary depending on the details of the type system.

- MinML predicts the form of values (boolean? function? integer?)
- MinML guarantees that integers aren’t applied to arguments
Formalization of Type Safety

Type safety formalizes a coherence between the static and dynamic semantics of a programming language

- The static semantics makes predictions about the execution behavior.
- The dynamic semantics must comply with those predictions.

Theorem (Safety):
If $\emptyset \vdash e : t$ and $e \rightarrow^* e'$, then $e'$ is not stuck (i.e., either $e'$ is a value or there exists $e''$ such that $e' \rightarrow e''$.}

Formalization of Type Safety

Type safety formalizes a coherence between the static and dynamic semantics of a programming language

- The static semantics makes predictions about the execution behavior.
- The dynamic semantics must comply with those predictions.

Theorem (Safety):
If \( \emptyset \vdash e : t \) and \( e \rightarrow^* e' \), then \( e' \) is not stuck (i.e., either \( e' \) is a value or there exists \( e'' \) such that \( e' \rightarrow e'' \)).
Theorem (Safety):
If $\emptyset \vdash e : t$ and $e \rightarrow^* e'$, then $e'$ is not stuck
(i.e., either $e'$ is a value or there exists $e''$ such that $e' \rightarrow e''$.

A number of different ways to prove; we concentrate on a syntactic proof.

Prove type safety by showing two related properties:

- Preservation: A well-typed program remains well-typed during evaluation. (If an expression is well-typed and takes a step, then the stepped-to expression is well-typed.)
- Progress: A well-typed program is not stuck. (If an expression is well-typed, then it is either a value or it can take a step.)
Proving Type Safety

Theorem (Safety):
If $\emptyset \vdash e : t$ and $e \longrightarrow^* e'$, then $e'$ is not stuck
(i.e., either $e'$ is a value or there exists $e''$ such that $e' \longrightarrow e''$.

A number of different ways to prove; we concentrate on a syntactic proof.

Prove type safety by showing two related properties:

- Preservation: A well-typed program remains well-typed during evaluation. (If an expression is well-typed and takes a step, then the stepped-to expression is well-typed.)
- Progress: A well-typed program is not stuck. (If an expression is well-typed, then it is either a value or it can take a step.)
Proving Type Safety

Theorem (Safety):
If $\emptyset \vdash e : t$ and $e \rightarrow^* e'$, then $e'$ is not stuck
(i.e., either $e'$ is a value or there exists $e''$ such that $e' \rightarrow e''$.

Theorem (Preservation):
If $\emptyset \vdash e : t$ and $e \rightarrow e'$, then $\emptyset \vdash e' : t$.

Theorem (Progress):
If $\emptyset \vdash e : t$, then either $e$ is a value or there exists $e'$ such that $e \rightarrow e'$. 
Theorem (Preservation):
If $\emptyset \vdash e : t$ and $e \rightarrow e'$, then $\emptyset \vdash e' : t$.

Proof:
By induction on the evaluation derivation $e \rightarrow e'$
(with $\mathcal{P}(e, e') \equiv \forall t. \emptyset \vdash e : t \Rightarrow \emptyset \vdash e' : t$).

- \(\emptyset \vdash e'_1 : \text{num}\)
  
  (by induction hypothesis with \(\emptyset \vdash e_1 : \text{num}\))

- \(\emptyset \vdash e'_1 + e_2 : \text{num}\)
  
  (by Add typing rule)

- Other search rules are similar.
Proof of Preservation

How might the proof have failed?

Only if some evaluation step doesn’t behave like its typing rule. e.g.:

\[
\begin{align*}
n_1 &= n_2 \\ n_1 &= n_2 \implies 1 \\
\end{align*}
\]

\(\text{EQT}\)

\[
\begin{align*}
n_1 &\neq n_2 \\ n_1 &= n_2 \implies 0 \\
\end{align*}
\]

\(\text{EQF}\)

\[
\begin{align*}
\Gamma &\vdash e_1 : \text{num} \\
\Gamma &\vdash e_2 : \text{num} \\
\Gamma &\vdash e_1 = e_2 : \text{bool} \\
\end{align*}
\]

\(\text{Eq}\)

Preservation fails: In the case for \(\text{EQT}\), would have to show \(\emptyset \vdash 1 : \text{bool}\).
Proof of Preservation

Proof is by induction on evaluation derivation.

If an evaluation step is undefined, then Preservation still holds! e.g.:

\[
\begin{align*}
  n_1 &= n_2 \\
  n_1 = n_2 &\quad\text{EQT} \\
  n_1 = n_2 &\quad\rightarrow true
\end{align*}
\]

\[
\Gamma \vdash e_1 : \text{num} \quad \Gamma \vdash e_2 : \text{num} \\
\Gamma \vdash e_1 = e_2 : \text{bool} \quad \text{EQ}
\]
Theorem (Progress):
If $\emptyset \vdash e : t$, then either $e$ is a value or there exists $e'$ such that $e \rightarrow e'$.

First, need a supporting lemma.
The type of a closed value determines its form.

Lemma (Canonical Forms):
If $\emptyset \vdash v : t$, then
- if $t = \text{num}$, then $v = n$
- if $t = \text{bool}$, then $v = \text{true}$ or $v = \text{false}$
- if $t = t_d \rightarrow t_r$, then $v = \text{fun}f(\chi : t_d) : t_r \triangleright e$

Proof:
By induction on the derivation $\emptyset \vdash v : t$. 
Theorem (Progress):
If $\emptyset \vdash e : t$, then either $e$ is a value or there exists $e'$ such that $e \rightarrow e'$.

Proof:
By induction on the typing derivation $\emptyset \vdash e : t$
(with $\mathcal{P}(\Gamma, e, t) \equiv \Gamma = \emptyset \Rightarrow \exists v. \ e = v \lor \exists e'. \ e \rightarrow e'$).

- **Num:**

  \[ \emptyset \vdash n : \text{num} \]

  Show \( n \) is a value.

  Immediate (\( n \) is a value).
Proving Progress

- Num:

  \[ \begin{array}{c}
  \emptyset \vdash n : \text{num} \\
  \hline
  \text{Num}
  \end{array} \]

  Have \( \emptyset \vdash n : \text{num} \).

  Show \( n \) is a value.

  Immediate (\( n \) is a value).
Theorem 1: Let $e_1$ and $e_2$ be two expressions of type \texttt{num}. If $\emptyset \vdash e_1 : \texttt{num}$ and $\emptyset \vdash e_2 : \texttt{num}$, then $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Proof: Let $e_1$ and $e_2$ be two expressions of type \texttt{num} such that $\emptyset \vdash e_1 : \texttt{num}$ and $\emptyset \vdash e_2 : \texttt{num}$. By the \texttt{Add} type rule, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$. Therefore, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Theorem 2: Let $e_1$ and $e_2$ be two expressions of type \texttt{num}. If $\emptyset \vdash e_1 + e_2 : \texttt{num}$, then $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Proof: Let $e_1$ and $e_2$ be two expressions of type \texttt{num} such that $\emptyset \vdash e_1 + e_2 : \texttt{num}$. By the \texttt{Add} type rule, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$. Therefore, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Theorem 3: Let $e_1$ and $e_2$ be two expressions of type \texttt{num}. If $\emptyset \vdash e_1 + e_2 : \texttt{num}$, then $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Proof: Let $e_1$ and $e_2$ be two expressions of type \texttt{num} such that $\emptyset \vdash e_1 + e_2 : \texttt{num}$. By the \texttt{Add} type rule, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$. Therefore, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Theorem 4: Let $e_1$ and $e_2$ be two expressions of type \texttt{num}. If $\emptyset \vdash e_1 + e_2 : \texttt{num}$, then $\emptyset \vdash e_1 + e_2 : \texttt{num}$.

Proof: Let $e_1$ and $e_2$ be two expressions of type \texttt{num} such that $\emptyset \vdash e_1 + e_2 : \texttt{num}$. By the \texttt{Add} type rule, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$. Therefore, we have $\emptyset \vdash e_1 + e_2 : \texttt{num}$.
Add: 

\[
\begin{align*}
\emptyset & \vdash e_1 : \text{num} & \emptyset & \vdash e_2 : \text{num} \\
\hline
\emptyset & \vdash e_1 + e_2 : \text{num}
\end{align*}
\]

Have \( \emptyset \vdash e_1 + e_2 : \text{num} \)
and \( P(\emptyset, e_1, \text{num}) \) and \( P(\emptyset, e_2, \text{num}) \).

Show there exists \( e' \) such that \( e_1 + e_2 \rightarrow e' \).

(1) \( e_1 = v_1 \) or (2) \( e_1 \rightarrow e_1' \) (by induction hypothesis)
(3) \( e_2 = v_2 \) or (4) \( e_2 \rightarrow e_2' \) (by induction hypothesis)

\[
\begin{align*}
e_1 + e_2 & \rightarrow e_1' + e_2 & \text{(by ADDL evaluation rule, if (2))} \\
v_1 + e_2 & \rightarrow v_1 + e_2' & \text{(by ADDR evaluation rule, if (1) and (4))} \\

\(v_1 = n_1\) (by Canonical Forms lemma with \(\emptyset \vdash v_1 : \text{num}\), if (1))

\(v_2 = n_2\) (by Canonical Forms lemma with \(\emptyset \vdash v_2 : \text{num}\), if (3))

\(n_1 + n_1 \rightarrow n\) (by Add evaluation rule with \(n_1 + n_2 = n\), if (1) and (3))
Cases for conditionals and applications are similar:

- use induction hypothesis to generate multiple cases
- use search rules when one sub-expression takes a step
- use Canonical Forms to show that primitive rules can be applied
Proof of Progress

How might the proof have failed?

Only if some evaluation step is undefined. e.g.:

\[
\begin{align*}
\frac{n_1 = n_2}{n_1 = n_2 \rightarrow \text{true}} & \quad \text{EQT} \\
\Gamma \vdash e_1 : \text{num} \quad \Gamma \vdash e_2 : \text{num} \\
\frac{}{\Gamma \vdash e_1 = e_2 : \text{bool}} & \quad \text{EQ}
\end{align*}
\]

Progress fails: In the case for EQ with \( e_1 = n_1 \) and \( e_2 = n_2 \) and \( n_1 \neq n_2 \), we cannot take a step and \( n_1 = n_2 \) is not a value.
Proof of Progress

Proof is by induction on typing derivation.

If there is no typing rule for an expression form, then Progress still holds!
Type safety expresses the coherence of the static and operational semantics of a programming language.

A standard technique for proving type safety is via

- preservation
- progress

A type safety proof exhibits whether we have a sound language design and (if not) where to fix problems.
