

# Formal Verification of Monadic Computations

Steve Zdancewic

Reasoning about monadic programs in Coq

Imp

Syntax  $\rightarrow$  inductive defs in Coq

\* Can step through the defs step by step in literal Coq

$\langle \{ \dots \} \rangle \rightarrow$   
 $\uparrow$   
parse these as Imp code.

$\langle \{ \dots \} \rangle \cong \langle \{ \dots \} \rangle$  program equivalence

Tactics:

cbn. : call by name

Q How much can be automated by using advanced tactics?

Yes

Q Can we run the program in Coq?

How we represent the program  $\leftarrow$  has trade offs

$\wedge$   
Depends on

Imp can be run.

Memory mem: string  $\rightarrow$  mem

( $! \rightarrow 0$ ) all-zeros map

Fixpoint: recursive fns.

Booleans and number exprs are pure in Imp.

Problem: eval for commands does not necessarily terminate  
(bc of while)  
It's not total!

$\rightarrow$  specify using relations instead.

st  $\xrightarrow{[cmd]}$  st' <sup>Large</sup> ~~small~~ step semantics.

In Coq:

Inductive eval: com  $\rightarrow$  mem  $\rightarrow$  mem  $\rightarrow$  Prop

Q: Diff betwn Inductive and Fixpoint?

$\uparrow$   
defines datatype

$\uparrow$   
inductively defined function  
must be total!

Drawbacks of large-step: need to do induction on derivations  
~~defined inductively~~ instead of ~~on~~ syntax.

Q: Can we do small-step?

can be made to work, but need to deal with indices everywhere. diff design space.

# MONADS

Large-step: mem

Fixpoint:

let  
let  
st

mem  $\rightarrow$  mem  
 $\uparrow$  init state  $\uparrow$  final state

S  $\rightarrow$  S  
 $\uparrow$

state\_bind

A generalization

let x := m

Q: Is there

Yes, not

Q: monad laws

Unbundle proof

pure in Imp.

does not necessarily terminate  
(bc of while)  
It's not total!

lead.

step semantics.

mem  $\rightarrow$  Prop

and Fixpoint. ?

$\uparrow$   
inductively defined function  
must be total!

do induction on derivations  
of ~~the~~ syntax.

need to deal with indices

# MONADS : "well-behaved sequential composition"

Large-step : need explicit plumbing for intermediate ~~step~~ <sup>states</sup>.

$$st = [a_1] \Rightarrow \underline{st'} = [c_2] \Rightarrow st''$$

Fixpoint :

$$\begin{aligned} &\text{let } \underline{st'} := \dots st \text{ in} \\ &\text{let } \underline{st''} := \dots \underline{st'} \text{ in} \\ &\underline{st''} \end{aligned} \quad \text{plumbing!}$$

$$\begin{array}{ccc} \text{mem} & \rightarrow & \text{mem} \times \text{nat} \\ \uparrow & & \uparrow \\ \text{init state} & & \text{final state, aux. answer} \end{array}$$

$$\begin{array}{c} S \rightarrow S \times B \\ \uparrow \\ \text{error} \end{array}$$

$$\begin{array}{ccc} \text{state\_bind} & (m : \text{state } S \ A) & (k : A \rightarrow \text{state } S \ B) \\ \uparrow & \uparrow & \uparrow \\ & \text{some computation} & \text{continuation} \end{array}$$

A generalization of let

$$\text{let } x := \underline{m} \text{ in } \underline{\text{ret } x}$$

Q Is there any reason to implement ret as a notation ~~not~~ <sup>instead of</sup> a function?

Yes, not all "ret" are ~~ret~~ functions.

Q monad laws?

Unbundle proof components req best practice in Coq.

Q. Is monad bad for modelling concurrency?

over-serialized computation, so yes  
might want to relax

but still useful in the sequential part.

let is associative.

"let-hoisting". "let-lifting" ← also called.

↗ ~~let-ye~~

In order to prove this law, also need to prove that capture avoidance  
~~variable capture~~ is handled correctly.

With Monad laws, can prove program equivalence.

Tomorrow: what does this "=" mean?

functional-extensionality ← not necessarily the right way.

Define equivalence over behaviors.
